Rupia is a bilious disease accompanied with small bullae, the bases of which are inflamed. The bullae are not numerous but flat and full of a serous fluid, which becomes thick, puriform, or sanguinolent, and drying up forms blackish thin or prominent crusts. It is commonly developed on the legs, sometimes on the loins or thighs. It attacks children that are of a delicate constitution, and persons weakened by other diseases. The scrofulous are peculiarly liable to it, and it comes on after hard living, insufficient food, exposure to cold and violent courses of life. It is generally indicative of an imperfect state of nutrition, and the treatment consists not so much in applications to the diseased skin, as in giving tone to the system by nutritious food, and tonic and alterative medicines.

Ecthyma (Pustulosa Scale) is a non-contagious inflammation characterized by large pustules raised upon a hard circular base, and covered with a crust. The pustules are of such large size, the phlyaxis of Willan, so that ecthyma bears the same relation to pustular diseases that rupia does to vesicular ones. In some stages in fact it is difficult to distinguish one of these diseases from another. Willan describes four varieties of ecthyma, but Rayer recognizes but two, acute ecthyma and chronic ecthyma. Acute ecthyma is a comparatively rare disease; it generally appears on the neck and shoulders, and runs its course in a few days. In this form it requires little treatment; light diet, diluent drinks, milk purges, and warm or cold applications to the part will suffice.

There are the same kinds of symptoms which discharge their contents in the course of two or three days, leaving behind them thick brown adherent crusts, which sometimes fall off, leaving an ulcer behind, but more frequently remain adherent. To form may be gradual or abrupt, and is usually produced by some external agent, and is simple or syphilitic and cutaneous, and is frequently modified by a syphilitic taint. Just in proportion to the intensity of the constitutional derangement will be the duration and extent of the eruption. In its treatment the general health must be especially attended to; it is a more disease indicating a want of action than of increased action, and alteratives, tonics, nutritious diet, change of air, and sea-bathing are more beneficial than any other kind of treatment.

Acne (Guttae roseae, Rose-Drop) is a chronic inflammation of the skin characterized by an eruption of small pustules surrounding a hard and inflamed base. They are generally observed on the face, neck, and shoulders, and are frequent on the arms and neck. The pustules are sometimes single, constituting the simple form of the disease; at other times they become hardened and the whole skin becomes red, where the disease takes the form of a red eruption, which is often seen in the oil-tubes, and arises from an obstruction to the performance of its functions, which produces inflammation. The oil-tubes of the face are very liable to obstruction from exposure to the air and atmospheric changes, and may be frequently observed tipped with a little black spot, and when pressed they give out a quantity of their oily secretion in the form of a little mappet. They were at one time supposed really to possess some medicinal virtue, but this is now considered by some to be the case with the mares of oil in question, it is now known that a little acrid takes up its abode in these oil-tubes, and is well known to zoologists under the name of Demodex Folliculorum. This little insect may then in some instances be the exciting cause of acne.

In the treatment of acne, regard must be had to the general health. It is frequently connected with a diseased state of the gastro-intestinal mucous system, which requires attention. Where it is connected with general debility from a rapid growth, or with a scrofulous constitution, tonics and alteratives with sea-bathing and regular exercise will be found of service. In those cases where the disease is caused by cold, sodium, and mercury, have been found most efficient. Where the face is much swelled and inflamed, fomentations will be of service previous to the use of the astringents.

Lichens which are produced by the simultaneous or successive eruptions of red itching pimples, scattered or disposed in groups over the whole body. It is in the adult which Strophulus is in the child. [BRITAIN, E. C. G.]

Diseases of the skin are very numerous and peculiar, but in the case of the majority which occur they arise from the neglect of some of the conditions necessary for the health of the skin. These conditions in general are, good nutritious food, which supplies the skin with all the necessary ingredients; warm clothing, especially during changeable and cold weather; constant and regular exercise, so as to keep the skin as an excretory organ in perfect order; and daily ablution of every part of the body, without which and the occasional use of soap it is vain to expect to be free from many forms of skin disease.

SKY is a name commonly applied to the infinite space which surrounds the earth, and of which the visible portion, above the horizon of a spectator on any part of the earth's surface, appears to have the form of a coruscate segment less than a hemisphere. [ESTIMATION OR OBJECTS, F. C. B.]

The earth is surrounded by the atmosphere, which is charged with vapours and terrestrial particles; and by the reflections which, in consequence, the rays of light experience in passing to the spectator, the sky assumes the variously coloured tints which it is so often described as having.

It is known from many experiments that pure air is devoid of colour; and the observations of M. de Saussure (Voyages dans les Alpes) have established the fact that, in an atmosphere unmarked by the presence of smoke, the sky is blue. The height of the sky, which is equal to the space visible, then seems to us to extend in all directions above the highest object which is visible, whether this object be a mountain, a cloud, or a cloudless space of sky.

When the sun has considerable elevation, the rays of light which in this part of the atmosphere are almost parallel, but diurnally to its surface, undergo scarcely any change of direction; but, with respect to the light from the sun which enters obliquely into the atmosphere, the violet and blue rays, or those rays which are more refrangible than the red, are bent, while the red rays, are partially arrested in their course, and are reflected in abundance to the earth; they thus, when the atmosphere is nearly free from clouds, give to the parts of the sky which are remote from the apparent place of the sun an azure tint.

The blue colour of the sky about the zenith increases in proportion as the sun is nearer the horizon; the rays then fall with greater obliquity upon the parts about the sun, and, at the same time, the blue rays in the beams of light
which traverse the atmosphere in directions nearly parallel to the horizon are absorbed, so that those only, as the yellow and red, which have greater momentum, arrive at the eye of the spectator; and hence it is that the blue tint of the sky is found to increase in intensity as the spectator ascends above the general surface of the earth. On the top of high mountains, at a distance of several miles from the horizon, one can observe the blue rays which, after reflection in the atmosphere, enter the eye is very great; and the blueness at length becomes a deep blue-ground on which the stars appear to shine at all times. At the appearance of the moon, is marked by the absence of the moon. It is hence evident that if it were not for the insensible reflections of the light from the sun or moon, which take place in the atmosphere, total darkness would prevail from the instant of sun-set to that of sun-rise; and even during the day, darkness would ensue, so that the stars would become visible, every time that the sun is obscured by a cloud.

That the blue tint of the sky is caused by light reflected in the atmosphere is abundantly evident from the fact that the light of the sky is found to be polarized: this quality in light, being a result of its reflection. Dr. (Sir David) Brewster, who has been so much interested in the subject, considered that the light of the sky consists of two parts, one blue and the other nearly without colour; and he discovered that these have different directions of polarization. (Treatise on New Philosophical Instruments, p. 946.)

The hypothesis that the saure colour of the sky is caused by reflections of blue rays, was at one time objected to on the ground that the shadows of opaque objects, placed on white paper and exposed to the sun's light, should always appear to be blue, since the part of the paper which is in shadow can only be visible by the light of the sky reflected from thence. This phenomenon is, in fact, frequently observed; but M. de Sasaure, while admitting that he has often perceived the shadows of objects to be bluish in the mornings and evenings on the general surface of the earth, states that in alpine regions, where the sky is intensely blue, the shadows of objects never appear to be so: he adds that, of fifty-nine observations made for the purpose of ascertaining the colours of shadows on the mountains, thirty-four showed them to be a pale violet, eight showing them to be black, six a pale blue, and once they appeared to be yellowish. It may be inferred, therefore, that shadows cast by opaque objects are so much affected by the colours of the neighbouring objects that the blue shadow of an object is thrown by stars, which they receive from the light of the sky. [ACCIDENTAL COLOURS, P. C. S. To the like interference must be ascribed the variously-colored shadows which were observed by M. E. Chevreul and M. M. Berlio, Mémoires de l'Académie des Sciences, 1748.]

Between the tropics the transparency of the atmosphere is far greater than it is, in general, in regions beyond them towards the north and south. For in the northern and southern parts of the earth the sun is almost always above the horizon, and the light which it gives is strong, and the atmosphere is thin:

For the description of an instrument invented in order to ascertain the intensity of the blue colour in the sky, see CRANSTON, P. C. S.

SMEDELEY, EDWARD, Reverend, was born about the year 1783, and was the son of the Rev. Edward Smedley, who had been the head of Westminster school for nearly half a century. The elder Smedley was the author of 'Eriu, a Geographical and Descriptive Poem,' published by subscription in 1610. His son was educated at King's School at Westminster in 1800; and thence he removed in due course to Trinity College, Cambridge. He took his degree of B.A. in 1809, as tenth Junior Optime, and, having obtained one of the Member's Classical Prizes, he was elected to a fellowship at Sidney College. He obtained no fewer than four of the 'Scotoamian Prizes for English poems; the first on the Death of Beau and Jonathan, 1814; the second, on Jephtha, 1815; the third, on the Marriage at Cana, 1827; the fourth, on Saul at Endor, 1828.

In 1829, he was called by Bishop Tomline to a prebend in the cathedral church of Lincoln, the value of which, however, was only 14l. a year; and this was the only ecclesiastical preferment he and England. Besides his Satyric Prize poems, he was the author of a poem entitled 'Prescience,' and of some others; and also of a 'History of the Reformed Religion in France,' in five vols. 8vo., and of one volume of his History of France. He contributed several articles on French subjects to the Edinburgh Review, and to the superintendence of the Society for the Diffusion of Useful Knowledge. At the time of his death he was editor of the 'Encyclopaedia Metropolitana,' and he contributed several articles on French subjects to the earlier volumes of the present work. His death took place at Dulwich on the 29th of June, 1836.

SMIRKE, ROBERT, R.A., of Greenwich, is the Nestor of the Royal Academy, of which he was a member for fifty-three years, died at his house in Ordnborough Street, Regent's Park, January 5, 1845, in his ninety-fourth year: he was born in 1724.

Smirke, originally a painter of coach-panel, was one of the most distinguished of the English genre painters, and had indeed no great rival before the time of his rise. His subjects are various, but his favourite subject was Cervantes; a great proportion of his pictures are from Don Quixote. Though so long a member of the Academy, he sent few pictures to its exhibitions, and only three before his election as a member, which were The Soldier, The Widow, and The Tournament, in 1796; and the Widow in 1797. He was elected an Academician in 1792, the year that Reynolds died, and he may be said as his presentation picture to the Academy. He contributed two pictures also in this year to the Academy exhibition: The Lover's Dream, and Musidora, from Thomson's Spring and Summer. In 1793 he exhibited The Battle of the Nile, from the Autumn of the same poet. Smirke designed much for booksellers, and for annuals and such works, and he was one of the contributors to Boydell's Shakespeare. He painted several pictures from Shakspeare, as Catherine and Petruchio, Juliet and Nurse, Prince Henry and Falstaff—'This chair shall be my state, this dagger my sceptre, and this cushion my crown!'—The Seven Ages; and others. From Don Quixote he painted Sancho's audience of the Duchess, The Countess Dolores discovering the cause of her grief to Don Quixote; The ceremony of board-washing performed by Don Quixote at the table of the Duke; Don Quixote addressing the Princess Dulcinea; and The Combat between Don Quixote and the Giants interrupted by the Innkeeper. The last time he exhibited was in 1813: the picture was styled 'Infancy.' In other classes, the following pictures are among his best works: The Infant Bacchus, which he formed of the coloured localities, the justifying Providence, from Farnell's Hermit; the Gipsy; the Fortune-tellers, &c. &c. Smirke was the contemporary of Sir Joshua Reynolds—he was the father of the present Sir Robert Smirke.

SMITH, SYDNEY, Reverend, was born in 1768, at the village of Woodford, in Essex. His father was a gentleman, whose residence was at Lydiard, near Taunton, in Somersetshire. Sydney was a very extraordinary boy, and always serene and intensely blue, while the clouds near the setting sun are brightly tinted with the prismatic colours. The skies of the south of Europe and some parts of North America are distinguished for their serenity and beauty; but, in these respects, they are said to be inferior to the skies over the islands in the Pacific Ocean.

The description of an instrument invented in order to measure the intensity of the blue colour in the sky, see CRANSTON, P. C. S.
SOC

Smith while in Edinburgh officiated at the Episcopal chapel there. In 1803 he removed to London, where he married the daughter of Bishop Pilkington, the Bishop of London, and resided in his residence. He became popular as a preacher at the chapel of the Foundling Hospital, and at other places. He also delivered lectures on polite literature with much applause at the Royal Institution, Albemarle Street, and was a regular contributor to the 'Edinburgh Review.'

Lord Erskine, when Lord Chancellor, gave him, in 1806, the rectory of Foston, in Yorkshire. In 1812 he was presented to the living of Waddington, by Lord Lyndhurst, and in 1831 he was appointed by Earl Grey one of the canons residentiary of St. Paul's Cathedral. Except a few years when he resided at his rectory of Foston, and during which his family was in the Hebrides, he remained in London, on the Subject of the Catholics to my Brother Abraham who lives in the Country, by Peter Plymley, his place of residence was London, where he associated with literary men and politicians of Whig principles, distinguished for his conversational powers, and consequently a frequent 'dinner out.' It is probable however that he kept within reasonable bounds of temperance, for he lived till the age of 77. He died at his house in Green Street, Mayfair, London, Feb. 21, 1844, and was buried in the Kensal Green Cemetery. He left the bulk of his property, which was large, to his widow and his son Wyndham Smith, M.P.

The Rev. Sydney Smith published 'Six Sermons,' Edinb., 12mo., 1800; 'Two Sermons,' 2 vols. 8vo., Lond., 1809; several occasional sermons and political pamphlets; and contributions to the 'Edinburgh Review.' In 1812 he published 'The Standard,' a monthly journal. He afterwards published his 'Pensioners,' 'The Works of the Rev. Sydney Smith,' 3 vols. 8vo., with a preface by the author and a portrait. The collection consists of his contributions to the 'Edinburgh Review,' Peter Plymley's Letters, and various occasional tracts. With respect to his contributions, he observes, 'I see very little in my reviews to alter or repent of. I always endeavoured to fight against evil, and what I thought evil then I think evil now. I am heartily glad that all our disqualifying laws for religious opinions are abolished, and I see nothing in such measures but unmarked good and real increase of strength to our establishment.' When he wrote this however, 'all our disqualifying laws' had not been abolished, as may be seen by looking over the acts of parliament which is reprinted under the head ROMAN CATHOLICS AND JEWS, P. C. S.

Sydney Smith is a very effective writer; he has considerable argumentative power, united with wit, humour, and poignant satire. His style is clear and forcible, without any apparent aim at elaboration or polish. Two or three letters which he published in the newspapers shortly before his death against the publication of their debts by certain States of North America are as strong in argument, as pungent in satire, and as effective in style as anything which he wrote in less than 40 years. (Athenæum; Gentlemen's Magazine; Preface to the Rev. Sydney Smith's Works.)

SMOKE BALIS. [Lamb's Balis, P. C. S.]

SOCRATES. [After Socrates, P. C. S.]

SOCRATES OF Bologna, the ecclesiastical historian, was born at Constantinople towards the end of the fourth century. He was instructed in grammar and rhetoric by Ammonius and Helladius, of Alexandria, and afterwards followed the profession of scholastic or advocate, on which account he is generally designated as Socrates the Scholastic. He appears, however, to have abandoned this profession in order to devote himself to the study of ecclesiastical history. He is generally considered the most exact and judicious of the three compilers of the history of Eusebius [Eusebii, P. C.]; he is less florid in his style and more careful in his statements than Socrates of Crete [Socra, P. C.], and less judicious than Theodoret [Theodore, P. C.]. He is likewise the earliest writer of the three, and Socrates is supposed to have borrowed some what largely from him. His history extends from the year 300 to the year 392, and is called in his 'Historia Tripartita,' and was published for the first time as a continuation of Eusebius, by Robert Stephens, Paris, 1544, in fol. There is a good French translation of it by Bertrand and D'Arches, in four volumes, 1681, 12mo., and another in German, by J. C. Boisserée, Hamburg, 1781, 4to. The history is résumé in several handbooks; the five last are chiefly composed on the authority of Rufinus [Rufinus, P. C.], and on the relations be gathered from eye-witnesses of many of the events he records. The two last in the form of letters to their readers [Le Sear, P. C.], are somewhat dull, and the reader is permitted the middle-sirth; unfortunately for the truth of this

had omitted several of the principal circumstances in the life of this celebrated father of the Church. [ATHANASIUS, P. C.].

He therefore went to Rome to find out the established residence of St. Anianus and Livius, who, however, took occasion of inserting several valuable documents and formularies of faith which throw much light on the Arian heresy.

Though the most exact of the continuators of Eusebius, he has nevertheless allowed himself to fall into error on several important points. For instance, he confounds the Emperor Maximianus with Maximinus (b. 1, c. 1), a mistake the more extraordinary as he states himself, in the 'Historia Tripartita,' to proceed upon the minutes of the Councils to relate the principal events which took place in that city. 'The carelessness of writers of that age, says Gibbon, 'leaves us in a singular perplexity.' 'Hist. of the Church of Rome, c. 169, note 2,' Theodoret, and others, have not only been taken also respecting the number of bishops who refused to sign the creed drawn up at the Council of Nice (b. 1, c. 8), as it appears clearly from the acts of the council and the authority of St. Jerome, Theodoret, and others, that there were only two, not five, dissentients, as Socrates asserts. His statements respecting a law passed by the Emperor Valentinian authorizing bishoprics (b. 1, c. 51), on the occasion of his marriage with Justin, rests on no other known authority, and bears the semblance of a fiction rather than a fact. His account of church discipline has been severely criticized by Baronius, who has, however, despised the other Roman Catholic historians; but Vallesia in his life clearly shows that there is no reason for such suspicion. We may mention another principle which he has followed, in which the mind of Baronius may have tended to confirm the notion of his heterodoxy—that he is invariably adverse to every form of persecution on account of religious opinions—'qcarvcn à llywv àv év yapcflav peractayvoc, év v7iaxvovcris: and I call it persecution to offer any description of persecution to those who are quiet.' ('Hist. of the Church,' p. 104.) He is, however, very generally suspected of a leaning in favour of the schism of the Novatians, though he shows but little knowledge on the subject, and confounds Novatian, who was a priest of Rome, with Novatian of Africa. (NOVATIANI, P. C.). The date of his death is not ascertained.

SOEUR, LE, HUBERT. This excellent sculptor, a Frenchman by birth, according to Walpole, was the pupil of the celebrated John of Bologna. He came to England probably shortly before 1630, in which year he was then living in Bartholomew Close, and a son of his was buried on the 20th of June in the Church of St. Bartholomew the Great, in that year in the parish of the same name.

Le Soeur must have been a man of about fifty years of age in 1630, for John of Bologna died in 1609 in Florence at an advanced age, and Le Soeur must have visited Florence therefore prior to the beginning of the century when he was his pupil. The connection with John of Bologna, who was a native of Donay in Flanders, and his subsequent connection with Rubens in England, seems to indicate Flanders as the country of Le Soeur rather than France. Rubens is said to have designed the much-admired bronze or brass statue of William Earl of Pembroke in the picture gallery of Oxford, which was executed and cast by Le Soeur. William Earl of Pembroke was Chancellor of the University of Oxford from 1616 to 1630.

In 1633 Le Soeur cast the well-known equestrian statue of Charles I. at Charing Cross; it was cast in a spot of ground near the temple and put up before the commencement of the great civil war, it was sold by the Parliament to a buyer of the name of John Rivers, living at the 'dial near Holborn Conduits,' who had orders to cut off the head of the statue thereon, which is fixed into several old books; the five last are chiefly composed on the authority of Rufinus [Rufinus, P. C.], and on the relations be gathered from eye-witnesses of many of the events he records. The two last in the form of letters to their readers [Le Sear, P. C.], are somewhat dull, and the reader is permitted the middle-sirth; unfortunately for the truth of this
story, however, the saddle-girth is there, and further, Le Soeur can never have seen the statue set up, as he must have died several years before 1678. The figure is dignified and expressive; it is a faithful portrait, and so admirably defined in modelling; the hinder quarters are especially void of character and motion. The pedestal was made by Grinling Gibbons. Walpole speaks of a bust at Stonorhead by Le Soeur, which is in the collection of Lord Cobbe; but it is very numerous; the poet himself is said to have been painted under a dragon h is Romaine, three feet high on a black pedestal. It is mentioned in Vanderdoert's Catalogue of Charles the First's Collection. Le Soeur executed many other bronze or bronze works in England, but they are now all lost or destroyed.

(Walpole, Anecdotes of Painting, &c.; English Con
considerations.)

SOLIDITY is a condition of solid bodies in which the particles are held together by a cohesive power of small intensity: in consequence of this, such bodies change their figures upon the application of a small degree of force; and they do not recover their previous forms upon its removal.

This condition is the opposite of hardness, in which the particles are held together by a power of cohesion so great that they cannot be separated by any force which it may be convenient to apply to them. No body in nature is known to possess either of these qualities absolutely; but in contemplating the mechanical actions of soft bodies, balls of wet clay are generally used, while blocks of wood acting against one another, represent the direct action of hard bodies. In such cases the effects of hardness. Balls of glass or ivory, or steel springs, serve to show the mechanical actions of elastic bodies. (Collins on Perfection of Bodies, P. C. S.)

SOLIDUS is the name given by the Romans to a gold coin, minted at 1000, 900, 800, 700, 600, 500, 400 P. C., and the equivalent of the English sovereign. (The English, their Manners and Customs, Etc.)

SOLIMENA was the rival and at the same time the friend of Luca Giordano, and in 1676 he was left without a rival, and he raised accordingly the price of his paintings, which however in no way diminished the number of his commissions. His works, both in oil and fresco, are very numerous: they are the frescoes of the sacristy of the Stallion of San Filippo Neri in the church of the Oratorio: there are also, likewise by him, some others at Naples have been several times published. He was never married; his large property, which besides estates amounted to 500,000 scudi, went to his nephews, the sons of his brother Tommaso Solimena, who was a distinguished lawyer. During his long life Solimena appears to have made only two short visits to Rome. Of his numerous scholars the principal were Sebastiano Conca, Giuseppe Corrado, Ferdinando Sanfelice, and Francesco di Mura.

(Donizetti, Vie de Pittori, &c. Negoliati; Lanzo, Storia Pittorica, &c.)

SOUTHBY, WILLIAM, was born in London, November 30, 1730. He was the fifth son of Sir William South
by, K. G., and was educated at Eton and at Christ Church, Oxford. In 1753 he joined the army, and purchased a commission in the Tenth Dragoons, from which he immediately obtained leave of absence, and passed several months at the military academy at Angers for the purpose of studying the principles of his profession. He was afterwards appointed one of the secretaries to the king, and immediately afterwards quittd the army and purchased Bevis Mount, near Southampton, where he continued to reside for the next ten years, amusing himself with poetic studies and writing. In 1766 he made a pecuniary tour to Italy, with Sotheby, of which he published a poetical narrative under the title of 'A Tour through North and South Wales.' His mother died in 1750, and in 1751 he removed from Bevis Mount to London, where he settled in the Strand, and was giving however a considerable part of every year at the Good House, in Epping Forest, of which he was one of the master keepers. Soon after he settled in London he became a Fellow of the Royal Society, of the Antiquarian Society, and of the Diluenti Society; and was in the habit of receiving at his house persons distinguished in literature and politics without any regard to party distinctions.

The language and literature of Germany had been for some time advancing in favour in England. Taylor, of Norwich, had chiefly contributed to this result; and Southey's friend Spenser had translated Bürger's 'Luscinia' with more success than Taylor had previously. Southey studied the language, and in 1796 published a translation of Wieland's 'Oberon,' which immediately became popular. In 1799 he published a short poem on the battle of the Nile, and in 1800 a translation of the 'Georgics of Virgil.' In 1801 he ad
ressed Sir George Beaumont in a 'Poetical Epistle on the Encouragement of the British School of Painting.' In 1808 he published 'Orestes,' a tragedy, in the model of the Greek drama, accompanied by a mask, entitled 'Huron de Bour
deaux,' founded on the story of 'Oberon.' His next work, on which he was occupied the greater part of two years, and which appeared in 1810, was a history of the 'United Kingdom of South.' In 1810 he produced 'Constance de Castile, a metrical Poem, in Ten Cantos,' in the style of the 'Lady of the Lake' and 'Marmion.' In 1814 he republished 'Orestes,' together with four other tragedies. Sotheby tra
velled through France, Switzerland, and Italy in 1816, in company with Mr. Elmsley and Professor Playfair. He returned to England, and was appointed, in 1817, Professor of Greek in the University of Edinburgh. In 1817 he published a corrected edition of his translation of the 'Georgics,' together with the original text, and the translations of De Lille, Boer, Guzman, and Voss, in folio; of which the first and second editions, and several editions of Europe, and received medals from them in acknowledgment.

When he was in his seventy-eighth year he commenced a poetical translation of the 'Iliad,' of which he completed a portion only, before his death, which took place in Scotland with the summer and autumn of 1826. On his return to London he pursued his task with unabated diligence, and completed the 'Iliad' in September, 1830. He immediately commenced the 'Odyssey,' which was completed, without his life, in July, 1832. He died December 30, 1833, in the seventy-seventh year of his age. His eldest son William, who was a colonel in the First Regiment of Guards, died in 1818, in consequence of injuries which his constitution had suffered in the Walcheren expedition and the war in Spain. His third son George, who was assistant-resident at Nagpoor, in Hindustan, was killed in repelling an attack of the Pindareres, November 27, 1817. Another son, Hans, who had been in the civil service in India, died in London, April 27, 1827.

Besides the works already mentioned, Sotheby published, in 1808, a work for the use of the schools; and his versions of descriptions of Italian scenery, most of which were probably written while he was travelling in 1816-17, and a few other small compositions.

As to his minor poems, little impression on the public, and are now nearly forgotten. His thoughts are pleasing, but faint, and frequently indistinct, from the polished diffuseness of his style. He has little originality or strength of imagination, but he has great facility and elegance of diction and versification, and hence his poetical translations are among the best which have been made in English. His 'Oberon' is an excellent version of Wieland's romantic poem, tolerably close, and not inferior to the original for the original tongue. He could not read German. His version of the 'Georgics' seems to have been a favourite work, and to have occupied much time in correction and improvement, and is perhaps superior to any other which has been made in our language.

The folio edition was published at five guineas, and is a splendid specimen of typography. His versions of the 'Iliad' and 'Odyssey,' Cowper's blank-verse translation is the closest which has yet been made. Sotheby's is in rhyme. In 'Blackwood's Magazine,' April, May, July, and December, 1831, are four critical articles on Sotheby's 'Iliad,' written by Professor Wilson in his usual popular style, but with great skill, truth, and nicety of discrimination, in which the translation is examined and compared, as well as the translation of the first book of the 'Iliad' by Dryden, and that (also of the first book) which was made by Tickell in rivalry with Pope. Sotheby's now have a share of the criticism which the critics deal out to the different translators; but Wilson's own specimens of literal prose versions exhibit Homer more truly than any of the others, and are probably to must readers more interesting, and even more delightful to read.

(Annual Biography and Obituary for 1835.)

SOULAMIA (Soolumina is the name of the tree in the Moluccas), a genus of plants belonging to the natural order Polypales. It has 5 sepals, the 3 outer ones very small, the 2 inner large and concave. The petal is concave. The capsule spheric, indehiscent, compressed, corky, margined, and spotted. The seeds are large, black, hard, and flat. The fruit is composed, thin at the edges, dry, with 2 seeds in each cell resembling cucumber seeds, but smaller, each lying in a small cavity of the cell. The plant is introduced in gardens, and the mode of cultivating it is at present unknown.

(Don, Gardener's Dictionary; Lindley, Flora Medic.)

SOU, CURE OF. [BERRITF, P. C.]

SOULIA is a Bight, or bay, established on the southern shores of Australia. It extends, as fixed by the British government, from 132° to 141° E. long. From the coast, which at its western border occurs near 32° 30', and at its eastern near 38° S. lat., its boundary line runs due north to 34° 27' S. lat. and forms a considerable continent on the southern coast. On all sides three is encompassed by Eastern Australia, or New South Wales. Within its boundary are contained two large bays: Spencer's Gulf, and the Gulf of St. Vincent. The town of Port Napier is on the coast of the River Murray. Kangaroo Island, which lies before the entrance of the Gulf of St. Vincent, is also annexed to it. The area of the colony, according to a rough estimate, is about 3,000,000 square miles and, and it is about 100,000 square miles larger than France.

The western portion of the territoy is a mere waste. Near the western boundary-line the country along the sea- coast is covered with scrub. It is almost entirely destitute of grass, and also of water, except during the rains and a few days after they have ceased, when small quantities of water remain in the flat depressions for a short time. This country continues as far east as Streaky Bay, south of which there is some improvement. The shore is skirted by low sandhills; and at the back of them is a belt a few miles wide, whose surface presents a succession of low hills, wooded and grassy, but very stony and destitute of water, except what is left by the rains in the depressions between the sandy hummocks and the hills. This country, being the country of the plains, consists of a succession of level, flat, and low lands, without water, and with rich water, consists of a succession of level, flat, and low lands, without water, and with rich

On the southern shores of Australia, Streaky Bay and the head of Spencer's Gulf, lies a mountainous tract, exhibiting a succession of lofty ragged ranges, one behind the other, running from east to west, but terraced or north-west at their extremities. They are called Gawler's Range, and attain an elevation of about 2000 feet above the sea-level, but decrease as they advance further east. Those ranges are devoid of timber, and have a barren appearance, but are overgrown with prickly grass. There are no rivulets nor springs, but between the hills are small salt-water lakes, with miscellaneous plants growing round their margins; fresh water is only found after the rains in the cliffs of the rocks. The country north of Gawler's Ranges has not been explored.

The country situated on the western shores of Spencer's Bay is of a much better description. It contains Port Lincoln, the most extensive and the best harbor in the colony. It consists of three basins: Spalding Cove, Port Lincoln, and Boston Bay, in each of which there is not less than ten or twelve fathoms water, with a bottom of mudsandy sand; it is much frequented by the vessels of the public service. Round these extensive sheets of water are many large tracts of well wooded, and others grassy with single trees dispersed over them. It is calculated, that in the vicinity of Port Lincoln, there are the greatest number of good places for cultivation or pasture. The peninsula south of Port Lincoln is hilly, but well wooded, and has much good pasture ground, and also the country north of it to the distance of ten or twelve miles; but farther north the hills disappear and are followed by a low tract which extends along the shore, and is densely wooded with brush, among which are scattered a few small patches of grass. Water is only found near a few rocky elevations. At the back of this low and rather narrow tract is a moderately elevated table-land, whose edge is broken by deep gorges into portions resembling hills. The soil is a sandy red loam, greatly mixed with stones, and presents only here and there a little old without grass. There are no high trees, but patches of scrubby bushes, and a few small pines. No water has been discovered.

The waiting mentioned in the head of this article, Spencer's Gulf, with a rather narrow channel, separates it from Flinders' Range. This tract is quite level, and has a sandy soil almost without vegetation. Flinders' Range constitutes the western boundary of a mountainous tract of considerable extent. It occupies in width a considerable space from west to east, lying east of Spencer's Gulf. It may be said that this mountain tract terminates on the south of the heads of the channels of the Murray and the River Murray, but is turned into a higher summit at the mouth of the Murray, where, a higher summit occurs, Mount Bryan, 3000 feet high. From these parts it extends nearly due north, with a small declination to
In its natural state it resembles a park, the single trees standing at considerable distances from each other. In this part of the city, the town of Adelaide is situated. It is built on the southern border of the Torrens, a river which rises in the hills about six miles east of the town. It can be called a river only in the rainy season, when the hills are full, and the flat, the plain upon which the town lies, appears to be Mount Brown, not far from the head of Spencer's Gulf. Further north, the mountains decrease in elevation. Between these ridges there are plains of considerable extent, and the plains are covered with almost naked rock, generally sandstone, and without the least vegetation. The lower slopes are covered with dense brush, and the valleys with low shrubs, and occasional small patches of vegetation. The plains are watered by a brook, a stream, or a narrow-arm, which is sometimes dry. They are sandy, and are capable of cultivation. In a few places, patches of grass are found, but others are quite sterile. During the rains, and a short time afterwards, running water is found at a few places among the hills, but it does not appear that it reaches the plain at the foot of the hills.

This mountain-region, as already observed, terminates on the north near 39° 15' S. lat., its extremity is surrounded by a narrow and abrupt coast. This coast is composed of a thick deposit of sand with water and sandstone with islands. The first explorers of this region considered it to be a lake, and called it Lake Torrens. But it was found that these appearances were deceptive, and that the coast was a narrow or very narrow river. Not a drop of water was found, and the islands turned out to be mere low sandy shores, scantily clothed with wasted scrub on their summits. A salt crust is found at intervals on the sand, and a few pieces of salt appear to be drift timber are lying about. Not a blade of grass or any species of vegetation is visible, and the sand is loose and drifting. This desert is about 800 feet above the level of the sea.

The river Broughton may be considered the southern boundary of the barren mountain-region just described. This river rises on the declivities of Mount Bryan, and appears to be a considerable river during the rains. In the dry season its upper course consists of extensive reaches of water connected by a strongly running stream, into which several chains of ponds discharge their water during the rains. Lower down, the Broughton winds through some broken hills of an open but barren description, and here the water is lost in the sands; only water-holes are found at intervals. Still further down, the channel, though very wide and deep, is quite dry. After this, the river turns south, and is lost in the Gulf of St. Vincent.

South of the Broughton a few high hills are found, as the Razorback (2000 feet above the sea), and the Lagoon Hill (2000 feet), they soon sink much lower. The country becomes more hilly, and smaller, and is excellent for the grazing of sheep and cattle. Here the river is lost in the sandy deserts. The southern end of the Broughton have open, and are covered with grass, but the rest of the peninsula is better adapted to pasture.

The country of the colony is the country lying on the east of the Gulf of St. Vincent. The interior of this tract is hilly, but the hills do not attain a great elevation; the highest, called Mount Lofty, is about 1200 feet above the sea-level. This is the highest point on the eastern edge of the colony. The hills come down to the sea on the Gulf of St. Vincent, about three miles south of Holdfast Bay, and occupy the whole of the peninsula between the Gulf and the sea. This peninsula is generally watered with large timber trees, and between them are tracts of good land. Along the shores of the Gulf are low sand-hills, on which bushes grow. Between these down and the hills, there is a considerable patch of country which contains a great portion of land capable of cultivation.

The interior of the country, which, south of the parallel of Lake Victoria, extends from the sea to 141° E. long., is a desert; its surface being formed by a succession of low ridges of carbonate of lime, with occasional low wooded valleys which only shalvery bushes grows. At the sea-mouth of the Murray begins a narrow arm of the sea, which extends along the shore and parallel to them over an extent of more than a hundred miles. It is called Coorong, and extends from the open sea by a narrow strip of land covered with sand-bills.
downs of moderate elevation. At the back of the northern half of the Coorong there is a belt of grassy hills overgrown with succulent plants, and between them there are numerous shallow plains of moderate extent with a good soil; fresh water is found at a moderate depth under ground, rarely exceeding six feet. There is a belt of the rain forest on the north side of the desert, at the back of the southern half of the Coorong there is a succession of salt swamps and low shrubby hills. A low range, called the Wanblat Range, runs for twenty miles parallel to the coast-line of about thirty miles. Behind this range is an extensive fresh-water swamp, several miles across, which appears to be subject to annual inundations. The soil of this swamp is similar to that of the flats of the river Murray; the swamp small sandhills, well wooded and grassed.

The Coorong terminates near 35° 30' S. lat., but in the line of its continuation a number of lakes, which are separated from the sea not by sand-dunes, but by grassy flats. At the back of the lakes are several grassy plains with a good soil, and wooded hills. South of Cape Bernouilli (near 37° 30' S. lat.) the country improves. It consists of several ranges of wooded hills, generally running parallel to the shore, which are separated from each other by low level grounds, a great portion of which is subject to inundation; but the soil is excellent, and in many places these flats are dry and available for pasture or agriculture.

The southern portion of South Australia will certainly become a very valuable country. A line drawn from Rivoli Bay nearly due east to the boundary-line divides it from the desert in the north. Near the mouth of the river shore low narrow ranges of wooded hills alternate with grassy plains and a few swamps. In approaching the higher country plains occur, which are of considerable extent, and covered with luxuriant forests, consisting of trees of great size, blackwood, gum, stringy bark, and mahogany. They extend to the foot of Burr Range, a mountain-tract divided into several ridges, which cover a great extent of surface, and are pretty well wooded; the highest point of this line rises to about 1000 feet above the sea. Between this range and the isolated mountains called Mount Gambier and Mount Schank lies a well-wooded tract with large timber-trees, and an excellent soil. The two last-mentioned summits are of volcanic origin.

Three distinct craters are visible on Mount Schank, which is between 800 and 900 feet above the sea. Mount Gambier is higher, and has also a crater on its summit. The soil of this region is of the richest description, being mostly a black brown loam, and the vegetation luxuriant. The value of this country for settlers is still increased by having a good and safe harbour in Rivoli Bay.

Kangaroo Island, which lies before the entrance of the Gulf of St. Vincent, is about 80 miles long from east to west; and on an average about 20 miles wide, which gives an area of 1200 square miles. It rises from the sea to between 100 and 200 feet, and does not attain a great elevation, the interior being occupied by extensive plains. Close to the shore, within a quarter to half a mile from the sea, it is covered with a thick forest, but as soon as the coast is passed, the whole country presents itself, which is covered with grass, and there are often hundreds of acres without a tree. In these plains are numerous ponds, and near the shore, lagoons which are generally filled with fresh water, but some are salt. On the shores of Nepean Bay is a salt-lagoon, on the banks of which large masses of crystallised salt are found. It would seem that nearly the whole of the island is available for agriculture or pastureage. On its north-eastern shore is Neptune Bay, where vessels may ride in perfect security during the western gales.

It is true that by far the greater part of the territory of South Australia will never produce any food for man or animals, but a part of the country, which is towards the south, is several very good tracts of land. It is probable that one-twentieth of the whole will either be brought under the plough or used as pasture-ground for sheep and cattle. This would cover 16,000 square miles, a very considerable tract of land, and one which is probably available land.

As this country has only lately been settled, we are but imperfectly acquainted with its climate. No series of meteorological observations has reached us, and we must conjecture what can be learnt from some agricultural observations. The dry season begins at the end of August and continues to the end of March. In December and January, corresponding to our June and July, the country appears to be in its greatest depression, and the least breaks raise clouds of dust. During the wet season, from the epih of March to August, it rains frequently and sometimes very heavily. The long droughts, with which New South Wales has been so much visited, are not known in South Australia. It appears that the rain diminishes greatly the moment it has proceeded inland, and it is probable that it ceases entirely before it reaches the northern boundary-line of the colony. During the winter it rains but slightly, and the country is then green, and frequently in hard gales. In the dry season northern and north-eastern winds prevail. Frost has never been experienced, nor any fall of snow.

During the very cold season a great number of whales visit the coasts of the colony, and are chased by British, American, and French vessels. The black whale is most frequent, but the sperm-whale also occurs. The native animals are the kangaroo and wallaby, a small species of the large genus, the opossum, and the dingo, or Australian dog. Birds are numerous, and distinguished by their beauty. The emu, several kinds of parakeets, of cockatoos, partridges, and quails are common.

The most common sea-fowl are pelicans, black swans, wild ducks, divers, waders, coromans, and Cape-pigeons (Procellaria Capensis). Several kinds of fish are taken in the sea, as salmon, mappers, porpoises, and large and small sharks. There are several kinds of snakes and lizards; among the latter the iguana, which is eaten; among shell-fish, oysters and periwinkles are mentioned as plentiful.

The colonists have imported horses from Tasmania and New South Wales, and small ponies from the Indian Archipelago; cattle and sheep from the Cape, Tasmania, and New South Wales; hogs from New Zealand. Poults are common, both the common species and the larger one from South America; the former is valued for its flesh, the latter for its breed of the bull-dog and greyhound, and used for chasing the emus and kangaroos; such a dog is often sold for 25 or 30 pounds sterling.

The woods of South Australia contain many large trees, but the timber is not much valued; and this article is imported from New South Wales and New Zealand. All kinds of grain have been introduced, and appear to succeed pretty well; maize grows well, and also potatoes; potatoes, water-melons, pumpkins, and cucumbers attain an uncommon size, and also cauliflower. Onions are cultivated to a great extent in Kangaroo Island. Our fruit-trees do not appear to grow well, except the peach, and there is a small kind of lemon; for apples, pears, &c. the climate appears to be too hot and dry. The vine has not succeeded, but probably it will. No edible fruit is indigenous, except some berries, which are eaten by the natives.

It appears that South Australia is rich in minerals. Iron ore has been found in many places, especially in the deserts; but it will probably never be turned to account, for want of fuel in the interior. Copper-ores have also been discovered in places in the vicinity of the settlements; and a quantity has already been shipped for England. It is stated that this ore is about 15 per cent. of copper; it is found in large masses. There are numerous deposits of salt in the deserts; and there is also a salt-lagoon on Kangaroo Island, and others on the coast of the colony which lies to the east of Lake Victoria.

The natives of South Australia, like those of New South Wales, belong to that race which is called Negro Australian; but it appears they have not yet attained an equal degree of civilisation with the native population of the eastern coast of Australia. This however may partly be the effect of the shorter duration of their communication with Europeans. When their hunger is satisfied, nothing can induce them to work, but when pressed by want of food they are ready to do any kind of labour for the colonist, especially carrying water or wood. It seems therefore that by able management they perhaps could be accustomed to some regular work, especially some of those kinds of occupation which are at present done by the natives. Though it appears certain that all the natives of the southern and eastern coast of Australia speak the same language, a marked difference exists in the dialects spoken in different parts of South Australia, and the whites having settled in the territories of South Australia: one is spoken by the few isolated families which live in the eastern districts west of 136° E. long.; another by the tribes inhabiting the vicinity of Port Lincoln; a third by the Aborigines on the coast about the banks of the Murray River. A native of King George's Sound, in West Australia, who accompanied Mr. Eyre in his expeditions, did not understand the language spoken by the other tribes, and that of the whites was so different as to enable him to distinguish the three; and this was before any white had set foot on the shores of South Australia. The settlement of Adelaide was founded in 1836; but six or nine months previously some families had settled on
Nepoc Bay, on Kangaroo Island, at a place called Kingscote. At first the emigration to this colony was very great, and in 1844 the number of white population was estimated at 15,000. In 1838 the colonies of Port Phillip and New Zealand were founded; which offered greater advantages to the settler; and the current of emigration ran to those countries and some very few have gone to South Australia. The white population at present probably does not exceed 20,000 individuals. The greater number of them are settled in the fertile country in the vicinity of the town of Adelaide. The traffic to and from South Australia is carried by the steamer Furneaux, which runs to and from Melbourne, about once a month.

SECOND SEA BUBBLE. The original conception and establishment of the South Sea Company was a project of Queen Anne's minister, Harley (afterwards Earl of Oxford), secondly he was a man of great weight in the House of Commons, and the object was to provide the means for paying interest at 6 per cent. upon, and eventually discharging, certain arrears which had accumulated upon the navy, victualling, transport, ordnance, and other departments, amounting, together with a new loan of 500,000l., to 9,471,325l. in all. For this purpose the crown was authorized by stat. 9 Ann. c. 21, entitled An Act for making good deficiencies and satisfying the public debts, and for creating a corporation to carry on a trade to the South Seas, and for the encouragement of the Fishery, &c., to incorporate all the persons interested in any of the bills, tickets, debentures, or certificates, or other public debts, deficiencies, or sums of money, intended to be provided for by the act, into a company; whose stock should consist of the said debts, or claims upon the public; and in which should be vested, from the 1st of August, 1711, for ever, the sole trade and traffic unto, and from all the kingdoms, lands, countries, territories, islands, cities, towns, ports, havens, creeks, and places of America, on the east side thereof, from the river of Aranoco to the southernmost part of Terra del Fuego; and on the west side thereof, from the said southernmost part of the said Terra del Fuego, through the South Seas, to the northermost part of America; and into, and from all countries, islands, and places, within the dominion of the crown of Spain, or which shall hereafter be found out or discovered within the said limits, not exceeding 300 leagues from the continent of America, between the southermost part of America, and the king of Portugal, and the crown of Surinam in the possession of the State-General of the United Provinces.

On the 8th of September, 1711, a charter was granted establishing the company by the name of The Governor and Company of the Merchants of Great Britain trading to the South Seas and other parts of America. The establishment of the South Sea Company went for a time under the name of the Earl of Oxford's masterpiece. It was anticipated that it would pour a continued stream of gold and silver into England from the mines of Mexico and Peru. In point of fact however, the trade which the Company carried on was from the first extremely insignificant. By the peace of Utrecht says Coxe (Memoirs of the Robert Walpole, i. 127), Spain and the Indies were confirmed to Philip V., that monarch was too jealous to admit the English to a free trade in the South Seas; and, instead of the Company's original success, the Company obtained only the Assiento contract (P. C. ii. 508), or the privilege of supplying the Spanish colonies of America with cargoes for thirty years, with the permission of sending to South America, for the amount and value of cargo, of the profits of which the King of Spain reserved one fourth, and five per cent. on the other three-fourths. But this disappointment was attempted to be counteracted by the depression in the South Sea Company had permitted two ships, in addition to the annual ship, to carry merchandise during the first year to the northern coasts of Spanish America, and a pompous nomination of the South Sea Company had paved the way to tremendous settle factories. But the grand benefits of this commerce were never realized. The first voyage of the annual ship was not made till 1717, and in the following year the trade was suppressed by Act of Parliament, with South Sea settle factories, and servants were seized and detained, notwithstanding the agreement in the Assiento which allowed, in case of a rupture, eighteen months for the removal of their effects.

This was the state of its affairs when, in the end of the year 1719 or beginning of 1720, the ministry of Sunderland and Stanhope seems to have entered into arrangements with the Company for having the whole amount of the National Debt, amounting to above 30,000,000l., transferred into its stock upon certain conditions. In conformity with what had been agreed upon between the parties, the Directors of the Company, on the 32nd of January, 1720, sent in their proposal to the House of Commons, engaging to pay 3,500,000l. for the liberty of increasing their capital by being thus constituted a sole national company. The members of the House of Commons disappointed in their expectation of the scheme being at once assented to by the House. It was suggested that other proposals should be invited; and Walpole, who had already expressed his desire in the Commons that he, and other persons, should be invited to become shareholders, it was agreed after some debate that the matter should be thrown open to competition. In consequence, on the 27th of February they sent in a second proposal to the House of Commons offering to pay 7,600,000l. for 3,300,000l. shares in a second proposal on the same day, which was supported by Walpole; but on the representations of Ataliba, the chancellor of the exchequer, it was resolved that the proposal of the South Sea Company should be accepted. Having regard to the effect was forthwith brought in, which, after several debates, passed the Commons on the 2nd of April, by a majority of 172 to 65, and the third reading of which was carried on the 7th in the Lords without a division. The same day it received the royal assent, and became the statute 6 Geo. i. c. 4.

The imaginary advantages accruing to the Company from this arrangement instantly produced a great rise in the market value of its stock. The promoters, Coxe, reported to the directors of the Company, that the effect was forthwith brought in, which, after several debates, passed the Commons on the 2nd of April, by a majority of 172 to 65, and the third reading of which was carried on the 7th in the Lords without a division. The same day it received the royal assent, and became the statute 6 Geo. i. c. 4.

SOU

of that of its rivals, procured writes of scarce fiction to be directed against certain of the other companies. The effect was instantaneous and universal. Alarmed by the apprehension of prosecutions by the law officers of the crown, the subscribers to the first plan had been specially hurried to take their shares for whatever they would bring, more eagerly than they had done to purchase them; the panic quickly spread through the whole extent of the share-market: the proprietors of the other companies, legally incorporated, submitted, by the general aspect of things around them, began to perceive that their stock too must have its point of highest elevation, from which it would as inevitably descend as would after a certain period the sun, when thrown into the atmosphere, and under the impression South Sea stock itself soon began to tumble down. By the 52nd of August it had fallen to 800; by the 30th it was at 750; by the 8th of September at 660; by the 20th at 410; by the 29th at 175. The bubble had burst.

It would require a great deal of space to tell the rest of the story of this remarkable financial infatuation and fever. A searching parliamentary investigation into the proceedings of the directors of the company followed in the next session, which produced many most scandalous disclosures, some of them affecting the most eminent persons in the country. Two directors were all indicted of the greater part of their fortunes; Addis, the chancellor of the exchanger, was expelled from the House of Commons; Craggs, the secretary of state, would probably have shared the same fate if he had not died of small-pox in the course of the proceedings, his son being carried round the streets of London in a disease almost as dangerous as that to which this land was with difficulty saved by the influence of Walpole; Stanhope, who was not supposed to be implicated in the fraud and bribery, burnt a blood-vessel while speaking upon the subject of Lords, and died of the next day. Not only the royal mistresses, but the Prince of Wales, and even the king himself, were believed upon strong grounds to have profited largely by stock which they were favourably placed for buying; and during the most disgraceful moment, all or the greater part of which they had obtained without purchase.

The storm thus raised was weathered and surged, and public credit restored, principally by the great financial talent of Walpole, who assumed the direction of affairs as first lord of the treasury and chancellor of the exchanger in February, 1721, and kept his post at the head of the government for the next twenty-one years. Even the affairs of the South Sea Company were by the measures which he adopted restored to some degree of real prosperity for a time; but its commercial operations never became of any consequence; and the members became at last mere government amnesties, till, all their claims having been satisfied, the company was finally dissolved only a few years ago.

It is not forgotten that the South Sea Bubble in England was coincident in point of time with the later stage of the famous Mississippi scheme of Law in France; but what real connection there may have been, if any, between the one and the other is, at present, an unimportant question.

(Pouthway's Historical State of the South Sea Company; Anderson's Chronological Deduction of Commerce; Macpherson's Annals of Commerce; Craik's History of British Commerce; Carey's Memoirs of Walpole; Malcolm's History of London; Parliamentary History; Statutes at Large, &c.)

SOUTH, ROBERT, LL.D. The little that there is to be told of the life of Southey beyond the account of his literary performances may most conveniently be given by itself in the first instance. He was one of several sons of a linen-draper in Wino-street, Bristol, where he was born, as the date is given by the 12th of August, 1774. Without according to the inscription on his tombstone, the 4th of October in that year. His first teachers were, a Baptist clergyman named Foon, said to have been a man of no ordinary ability, to whom he was sentwhen in the next, a Mr. Flower, at Corston, near Newton St. Loe; then a Mr. William Williams, a Welshman (something dropped into his mind by whomsoever, possibly, may have long after suggested the subject of his study). At last, in 1788, he was placed at Westminster school, the expense of his education from this time, it is intimated, being borne by Mr. Hill, a brother of his mother, who in other accounts however is called a Rev. Dr. Meredith, who, it may be supposed, was his patron. At Westminster, where however he had incurred censure for taking part in a rebellion against the head master, Dr. Vincent, in 1790, he was sent to Baliol College, Oxford, his uncle's intention being that he should enter the church. But it was almost unavoidable that his enthusiastic temperament should precipitate him into the so-called liberal opinions both in religion and politics which prevailed at this time. Being of promise, he was adopted both in France and in this country; in the former, on account of his extreme of free-thinking on both subjects; and in 1794 he left Oxford. He and a fellow-townswoman, a young Quakeress, were the first in this country to be used as models for the volume of poems, under the names of Bon and Moschus. It was soon after this too that Southey became acquainted with Coleridge. Lovell had married a Miss Fricker, of Bristol; and, in 1795, started on a visit through the Alps, by which day united themselves to her two sisters. The three had formed a plan to go out together to the wilds of North America, and there to set up what they called a Fanciscan, in which they were to live without either kings or priests, or any of the other evils of old world society, and to renew the patriarchal or the golden age. But this fancy was never attempted to be carried into effect. Southey soon after set out for Portugal with his uncle, the Rev. Mr. Hill (or Herbert), who had been appointed chaplain to the English factory at Lisbon. He returned to Bristol in the summer of 1797; in 1798 he removed to London, and entered himself a student of Gray's Inn; but he never obtained the usual, the law, and all that is further related of him for some years, is that he was again in the Peninsula in the years 1800 and 1801, and that on his return home in the latter year he went over to Ireland. In 1804 he was appointed Chancellor of the Irish Exchequer (other accounts say to Mr. Foster, that is, we suppose, the Right Hon. John Foster, who however did not become Chancellor of the Exchequer till 1804), but was not taken into the grave. In 1807 he was appointed Chancellor of the Irish Exchequer (other accounts say to Mr. Foster, that is, we suppose, the Right Hon. John Foster, who however did not become Chancellor of the Exchequer till 1804). This appointment agrees very well with the inscription on the monumental tablet commemorative of Southey in the church of Crathwaite, which indicates that he had resided nearly forty years at Greta Hall in that parish. Wordsworth had, we believe, taken up his residence in this lake country before Southey; and they were soon after joined by Coleridge, who however left them in 1810, leaving Mrs. Coleridge with Southey, whose hospitable roof also sheltered his wife's other sister, Mrs. Lovell, now a widow. Long before this Southey had abandoned his democratic and half-didactical style, and taken up with one diametrically opposite. For all the rest of his life, as it is well known, he was an ardent, uncompromising, and somewhat intolerant monarchist and churchman, promulgating and maintaining doctrines, which were in some respects even something beyond conservative.

In November 1813, on the death of Mr. Pye, Southey was appointed Poet Laureate; and in 1821 he received the degree of LL.D. at the University of Oxford. In 1824, the year of his death, he was presented with a tombstone, which was placed in Westminster Abbey, and with a large gift of money, besides a valuable library, which was afterwards disposed of by auction in London.

Southey was the father of five, and the grandfather of three, with property amounting to about 12,000l., in money, besides a valuable library, which was afterwards disposed of by auction in London.

Southey was the father of five, and the grandfather of three, with property amounting to about 12,000l., in money, besides a valuable library, which was afterwards disposed of by auction in London.

In 1796, Joan of Arc, an Epic Poem, 4to.

In 1797, Poems, 8vo.—Letters written during a short residence in Brussels, 4to, 2 vols.

In 1799 and 1800, The Annual Anthology (a miscellaneous collection of poetry, of which he was the editor and principal writer), 2 vols. 8vo.

In 1800, The Thalassa the Destroyer, a Metrical Romance, 2 vols. 12mo.

In 1803, Amadis de Gaul (a prose translation from the Spanish version by Garcia Ordóñez de Montalvo of that romance which had been originally written in Portuguese by Vasco de Lobreira), 4 vols. 12mo.—The works of Thomas Chatterton (In conjunction with Mr. Amos Cottle, the Life, originally printed in the second edition of the 'Bibliotheca Britannica,' being by Dr. G. Gregory), 3 vols. 8vo.

In 1804, Metrical Tales, and other Poems, 8vo.

In 1805, Madoc, a Poem, in Two Parts, 4to.

In 1808, The Chronicle of the Cid, Rodrigo Diaz de Bivar, from the Spanish, 4to.

In 1810, The History of Kehama, a poem, 4to.—The History of Brazil, vol. i. 4to.

In 1812, Omniana, 2 vols. 8vo.

In 1813, Life of Nelson, 2 vols. 8vo.

In 1814, For the commencement of the year 1814, 4to.—Odes to the Prince Regent, the Emperor of Russia, and the King of Prussia, 4to.—Roderick, the Last of the Goths (a poem), 4to.

In 1815, The Tempest; Carmen Nupiale (a poem on the marriage of the Princess Charlotte), 12mo.—A Poet's Pilgrimage to Waterloo, 8vo.

In 1817, Wat Tyler, a Dramatic Poem (written in a vein of ultra-Jacobinism, in 1778, and now surreptitiously published), 12mo.—A Letter to William Smith, Esq., M.P. (on the subject of the preceding publication), 8vo.—Morte Arthur (a reprint of Sir Thomas Malory's prose romance), with an Introduction and Notes, 2 vols. 4to.—History of Brazil, vol. ii. 4to.

In 1819, History of Brazil, vol. iii. 4to.

In 1820, Life of John Wesley, 2 vols. 8vo.

In 1821, A Vision of Judgment (a poem in English hexameters), 4to.—The Expedition of Orose and the Crimes of Agurillo (partially printed in 1812, in the Second Part of the Edinburgh Annual Register, for 1810), 12mo.

In 1822, Letter to the Editor of the Courier Newspaper, dated Keswick, January 5th, and published in the Courier of January 11th of the same year, and now appended by Lord Byron to his tragedy of the 'Two Foscari'), 8vo.—History of Henry Kirke White, vol. iii. 8vo.—History of the Peninsular War, vol. i. 4to. (an expansion of what had been originally published in the Edinburgh Annual Register, 1810, 4to.)

In 1824, The Book of the Church, 2 vols. 8vo.

In 1825, A Tale of Paraguay (a poem), 12mo.

In 1826, Vindiciae Ecclesiastica Anglicanae, &c., 8vo.

In 1827, History of the Peninsular War, 2 vols. 8vo.

In 1829, Sir Thomas More; or, Colloques on the Progress and Prospects of Society, &c., 2 vols. 8vo.—All for Love, or The Sinner well Saved; and The Pilgrim to Compottella, or A Legend of a Cock and a Hen, 12mo.

In 1832, Essays, Moral and Political, 2 vols. 8vo.—Selections from Southey, Prose, 12mo.—History of the Peninsular War, vol. iii. 4to.

In 1833, History of England, vol. i. 12mo, (in Lardner's Cabinet Cyclopaedia); completed in 5 vols. in 1840.

In 1834, Dr. Watts's Poems, with a Life of the Author (in Wordsworth's 'Sacred Classics'), 12mo.—The Doctor (anonymously, and never acknowledged, but believed to be Southey), vol. i. and ii. 8vo.

In 1837, The Poetical Works of Robert Southey, collected by himself, 10 vols. 12mo.—The Doctor, vol. iv. and v. 8vo.—Life of the Translator, post 4to. (according to Lowndes, who however gives no date).

To these works, making in all above a hundred volumes of various sizes, are to be added numerous papers upon history, biography, public morals, and general literature, published in the Quarterly Review, to which he was a constant contributor from its establishment in 1809, till head and hand would work no longer. He also wrote for some years the historical portion of the 'Encyclopaedia Britannica,' and contributed other matter to that work, which began to be published in 1810, and was discontinued in 1824. He was besides one of the most regular and voluminous of letter-writers; and the digestions of his letters are understood to be in existence, which it is to be hoped will, ere long, be given to the world. Some have already appeared in Robberda's 'Memoirs of the Life and Writings of William Taylor, of Norwich,' 2 vols. 8vo., 1843.

As a poet, Southey cannot be placed in the first rank even of the poets of his own time. Wordsworth and Coleridge, Shelley and Keats, Byron and Scott, Moore and Crabbe and Campbell, whatever differences of opinion there may be as to their relative merits or their positions in reference to one another, will be generally admitted to have each and all excelled more or less of a men of his day which was wanting in him. The light with which he was original and self-taught in them, seemed, even when it alone the strongest, to be only reflected light in him. In mere fertility he was equal to any of them. But his mind, although a teeming, was not an inventive or creative one. He returned a depot in it, but communicated to it comparatively little of any new nature or quality. His imagination might even be said to be both ample and gorgeous; still there was wanting the true spirit of the mystic, which distinguishes a real thing from a painted show. No natural human voice coming from the poet himself animated his verse; but rather an artificial sound, as from a flute or an organ. Such poetry may be both beautiful and grand, and majestic; but it cannot be called poetry, or live. For there is nothing so alien from and so fatal to poetry as any admixture of the mechanical. It acts like a dead substance imbedded in a living body. Witness such an instance as that of Darwin. There is much rhetorical splendour however in parts of Southey's poetry; especially in his 'Curse of Kehama,' and in his 'Roderick.' And some of his ballads and other shorter pieces, flowing on as they do in the easiest and purest English, are very happy.

In his prose writings the great merits of his style show all advantages. It is essentially a prose style, and one unsuited to poetry, at least to poetry of any high order, by some of the very things that contribute to his character excellence. Its facility and suavity, running into some degree of diffuseness; its limp perspicuity; its equality and smoothness; even its very unities, are unfitted for the true poet. In the latter case, the poet of the Peninsular War, the Bivar, and the Regent, the Life of Nelson (in 1813). Both in its merits and in its defects Southey's style may be compared to glass, which perfectly transmits the light, but refuses to conduct the lightning. It does not rise to any splendour of eloquence; it has little or no brilliancy of any kind; but whether for narrative, for exposition, or for animated argumentation, it was perhaps the most effective English style of the time. It combines in a remarkable degree a somewhat lofty dignity with case and kilomistic vigour, and is equally pliable to the expression of sprightliness and playful as of severe and indignant sentiment. He certainly was not nearly so great a thinker as he was a writer. He had no subtlety of intellect, and he took rather a passionate than a reasoning view of any subject that greatly interested him. Much of his political and economical speculation is now professedly dated as the intellectual, often by the most ardent of his admirers. But there can be no question that he was thoroughly honest and in earnest in whatever opinions he at any time professed. He was, by the universal testimony of his contemporaries, a man of the sincerest, gentlest, high-minded nature, and in all the relations of private life a man worthy of the highest estimation. (Memoir in Gent. Mag. for June, 1843; Dictionary of Literary Biography; Literary Gazette; Athenaeum; and the works mentioned in the article.)

SOWENS. [AYERS, P. C. S.]

SPACE, THEORIES OF EXPANDING, [TELEPUS, P. C. P., 163.]
SPALDING, SAMUEL, was born in London, on the 30th of May, 1807. He furnishes an example of success attended by no extraneous effort, or claim to notice, in the presence of any remarkable ability or aptness for its attainment. According to the testimony of his friends, it was only by means of great labour that he could perform his daily tasks with ease or rapidity in his steady and constant diligence. It was much even at this early period of his life from a sense of duty, the effect of moral and religious training, enabled him to acquit himself with great respectability; and the mode in which he always entertained this view, perhaps, appears to have done much towards forming those habits of unceasing application which constituted one of the strongest features of his intellectual character. At a suitable age he went to a public school; but his parents, being too deeply interested in the study of theology to allow him to enter the train of spending his life in a secular profession. He now examined the evidences of Christianity with the most assiduous care, and the work of Dr. Chalmers on this subject, together with the splendid discourses of the same writer on the relation of revelation to the discoveries of modern astronomy, inspired his mind with such elevated views of the grandeur of Christianity and the expensive benevolence of its design, that he resolved to devote himself to the pastoral office in the religious connexion to which he belonged, that of the Congregational Dissenters. He consequently applied himself with great ardour, theory and practice, to a study which he had to conduct, and to which he was destined, with a naturally feeble constitution, in which there is little doubt that the seeds of organic disease early existed. The object was the intellectual character, and one of his new relations, 'was benevolence.' In him it extended from the tree, which he would stoop to pick up lest it should be trodden on, to the highest order of beings. Whatever was capable of suffering or enjoyment excited his sympathy.

With a view to promote his object of qualifying himself for the ministry, Spalding devoted his time, for two years, to the study of the Greek and Latin languages, in private; and afterwards entered as a student at University College, London, where he made himself an exact Greek scholar. During his academic course here he obtained, in addition to high certificates of honour in other classes, five first prizes in the classes of Hebrew, French, Natural Philosophy, and the Philosophy of the Mind and Logic. Of the last subject his pursuit was ardent, his diligence and ability, as manifested in his essays and examinations, being such as to mark him out as a student of unusual merit. In the year 1839, symptoms of incipient pulmonary disease induced him to try the effect of a warmer climate, and he spent the winter in the South of France. On his return he underwent the examinations for the degree of Bachelor of Arts, at the University of London, in May, 1840. In the Transactions of the University, his name is mentioned with honour for his examinations in Animal and Vegetable Physiologist, and in the Hebrew and Greek objects of the Holy Scriptures. He is there recorded as having 'passed a distinguished examination' in Logic, the Philosophy of the Mind, and Moral Philosophy. In consequence of this success he was urged by the examiners to undertake the study of his subjects; and this encouragement encouraged him to compose his work, entitled 'The Philosophy of Christian Morals.' In the autumn of 1840 Spalding went to Italy, where he remained nearly two years. It was during this period that the above-mentioned work was written, the subject of which however had occupied his mind for many years. On his return to England, in 1842, he purposed superintending the publication of his Treatise, but was prevented by the progress of his disease; and as a last resource he tried a sea-voyage, and went to Cape of Good Hope, where he died on the 14th of January, 1845, about three weeks after his arrival. His work was published during the same year, by his friends, and entered by the late Mr. Spalding, to the space for any criticism of Spalding's theory of morals: we must restrict ourselves to a bare summary of his principal doctrines. They are as follows:-

(i) The primary notions of virtue and vice are derived from those feelings of like or dislike, which we experience in the view of conduct of others. These notions accrue new force and become more distinct in consequence of the sympathy which we experience in the review of our own conduct. The objects of moral obligation are a general virtue itself; and, secondly, the mode in which virtue ought to be displayed in the outward conduct. The great rule of action, which furnishes the ground of the virtue and vice, as inferred from the end and object of the various affections themselves. The notion of moral obligation is an immediate consequence of the testimony of our moral emotions. The great object of moral approbation is the principle of benevolence; from which is derived the sympathy of our nature. All other virtues are necessarily contained in this principle of benevolence; apart from which every sympathy itself is merely pathological, not moral. The moral character of man is not essentially, but radically, moral. Spalding's theory may be characterized by its referring conscience ultimately to emotion, not to moral judgment; by its ascertaining the necessity of there being other moral agents in the universe, not to its being derivable from any one; and by we can have the notion of virtue or of vice, and by its reduction of all the forms of virtue to the one principle of benevolence. Without pronouncing either one way or the other on the merits of this theory, we may well regret that it is not more likely, and that it abounds with passages of genuine power and beauty; and that it is characterized throughout by an elevation of thought and sentiment which distinguish it even among books on ethical subjects. The author writes with the glowing warmth of one whose heart is in his work, sometimes with an intense ardour of feeling. The book is therefore of a popular cast, though it often discusses principles ably and profoundly. It exhibits also in a striking manner the real harmony subsisting between the Christian precepts and the genuine dictates of the moral faculty, notwithstanding apparent or supposed discordances. It is wholly free from all sectarian and party feeling, and exhibits a social sentiment which was a distinguishing characteristic of the author's mind.

SPARTINA, a genus of grasses belonging to the tribe Chlorideae. It has upright 1-flowered spikes in races, the glumes usually acute, often long, and at the upper end of the spike unequal, the outer boat-shaped, compressed, red; the styles elongated, nerved, half-way up; the stigmas bifid, protruding at the summit. It is of British species, the S. anglica, S. alterniflora. The former grows on muddy salt-marshes, the latter has been found only on the mud-flats of the river Itchen at Southampton.

(Spalding, Manual of British Botany.)

MUDBEAT (from edwby, a spate, in reference to the form of the calyx), a genus of plants belonging to the natural order Bignoniaceae. The calyx is spathaceous, cleft and toothed or entire on the other side. The corolla is funnel-shaped, with a 5-lobed rather unequal limb. The 4 stamens are divided into 2 long and 2 short, with the addition of a fifth sterile filament. The capsule silique-formed, falcate, falsely 4-celled, and corky. The seeds are furnished with membranous wings. The species are erect shrubs or trees, rarely climbing shrubs. The flowers somewhat panicked, orange-coloured, yellow, or purple.

S. Rhoeas has wavy linear-lanceolate leaves, roundish downy leaflets, terminal erect racemes, and a much-berayed slender corolla. The shoots are covered with a whitish down. The racemes the length of the leaves. The flowers white and purple, more purple in the lower half.

S. officinalis has downy linear-lanceolate leaves, roundish downy leaflets, terminal erect racemes, and a much-berayed slender corolla. The shoots are covered with a whitish down. The racemes the length of the leaves. The flowers white and purple, more purple in the lower half.

S. Rosbrugghii has its leaves three in a wheel or scattered impari-pinnate. The leaflets from 4 to 5, in pairs, serrated and smooth, and a very small heart-shaped tooth at the base. The corolla is boat-shaped, and many-flowered. The fruit narrow and 4-celled. The calyx generally 2-parted, with the upper lip 2-cleft and downy. It is native of the Circassia. The branches are very spreading. The back grey, with a few sessile spots. The flowers large, rose-colored, and delightfully fragrant. The limb of the corolla nearly equal, and elegantly waved at the edges. This species is remarkable on account of its serrated leaves. The wood is employed for many purposes by the natives.

S. longiflora is an arboreous plant, and has large spreading terminal panicles, a bilabiate corolla, long-pendulous sub-cylindrical follicles, which are joined in pairs and variously curved. The flowers are large, yellow, and very fragrant. The follicles are very long. The wood of this tree is high-coloured, hard, durable, and of much use amongst the inhabitants of the hills about the coast of Coromandel and Malabar, where it is plentiful.

The species are splendid plants when in blossom. A mixture of loin and post suits them both, and cuttings will strike readily in any potting compost. They are elegant and decorative and as much as the magnolia. The peduncle of Mississippi is the type.

(Don, Gardener's Dictionary.)

SPATULARIA, a genus of fishes of the Sturgeon tribe, remarkable for the peculiar shape of their mouths, which are enormously prolonged and jaw-like in form. This peculiar structure is peculiarly the type.
SPEAKER. [Parliament, P. C.]

SPECIAL OCCUPANCY. (Occupancy, P. C.)

SPECIALTY, SPECIALITY DEBT, or debt by special contract, is a debt which becomes due or is acknowledged to be due by an instrument under seal. [Deed, p. 730.]

The cause of such a debt by simple contract is explained under SIMPLE CONTRACT.

Blackstone (iii. 464) considers a debt of record, that is, a debt which appears to be due by the judgment of a court of record, as 'a cause not being taken to deduce by the sentence of a court of judicature.' This is, however, an erroneous view of the matter. It is simply a rule of law that a debt for which the judgment of a court of record has been obtained is not payable over other courts.

SPECIFIC HEAT is the quantity of caloric which a substance of any kind absorbs, or which it gives out, when it undergoes a change of temperature; being determined, in a substance of any kind, with relation to the quantity which is lost in undergoing a like change of temperature. This designation, which is said to have been first used by the Swedish philosopher Wilcke, has nearly replaced the less proper one of Capacity of Heat which was given by Black, who first remarked that in order to bring different substances to equal temperatures of different quantities of heat must be applied.

Dr. Black considers that heat exists in all substances in two different states: one state he supposed to be that in which the heat is so united to the substance that it is in sensible or insensible, and the other to be that in which the heat is sensible, or is capable of being made evident to the senses, and of being measured by the thermometer; the former is that which is now designated specific heat. The term capacity for heat is considered objectionable, because it seems to imply that the heat existing in any substance is contained in the pores of the substance; and, if it were so, it should follow that the capacities of substances for heat are directly proportional to the porosities of the substances or inversely proportional to their densities, which is far from being the fact, though it is well known that the more dense substances contain smaller quantities of heat than those which are less so.

In determining the relative specific heats of two substances, either the substances when heated to a certain temperature are plunged in cold water and the augmentations which they occasion in the temperature of the water are observed, or the instrument called a Calorimeter [H. G. P., p. 92] is employed.

With this instrument, since the ice surrounding the heated substances which are separately introduced in it continues at a temperature expressed by 32° Fahr., till it is entirely melted, it is evident that the quantities of water (at 32°) arising from the dissolution of part of the ice by the different substances, whose temperatures had been previously raised to equal heights, must be proportional to the caloric lost by the ice in raising its temperature from 32° to its melting point, and thus the specific heats of the substances are determined. When, as is usual, heated water is the substance introduced in the calorimeter, the ratio between the specific heat of water and that of the substance is used.

If the body whose specific heat is to be determined is a solid, it is first heated to any convenient number of degrees of temperature, suppose 212° Fahr.; it is then placed in the calorimeter, and allowed to remain there till it is reduced to the temperature of ice (32°): then the quotient arising from the weight of the water obtained from the melting of the ice surrounding the body, divided by the product of 180° (=212° — 32°) multiplied by the weight of the body, will express the required specific heat.

The specific heat of water or any other liquid is determined by the calorimeter in a similar manner; the liquid heated to 212°, for example, being contained in a vessel of known specific gravity, and examined to ascertain the total quantity of water produced by the melted ice that part of it which, by experiment, is found to depend on the cooling of the vessel containing the liquid.

The specific heats of different solids, that of water at 212° being unity, were found by Hutton, using the following calorimeter:

<table>
<thead>
<tr>
<th>Substance</th>
<th>Specific Heat</th>
</tr>
</thead>
<tbody>
<tr>
<td>Platinum</td>
<td>0.00355</td>
</tr>
<tr>
<td>Silver</td>
<td>0.0087</td>
</tr>
<tr>
<td>Copper</td>
<td>0.00949</td>
</tr>
<tr>
<td>Iron</td>
<td>0.0198</td>
</tr>
</tbody>
</table>

The difference between the specific heats at different temperatures is ascribed to the dilations which the substances experience by an increase of heat: every change in the constitution of a substance is accompanied by a change of specific heat; a solid body, for example, has a smaller specific heat than the same substance in a liquid state. This is, therefore, a liquid solvent among the solids.

The specific heat of water being unity, that of ice is 0.9.

With respect to liquids, Lavoisier and La Place have given a table of their specific heats, of which the following is an extract:

<table>
<thead>
<tr>
<th>Substance</th>

</table>

The specific heats of gases are still subject to much uncertainty, though many attempts have been made by eminent chemists. During the struggle of Hamburg, in the winter of 1813-14, his parents took refuge with their family in the house of the banker Dehn, in Altona, where there was a good collection of pictures, and where Erwin made the acquaintance of the painter J. W. von Stroud, who was also living in the banker's house, and had a studio there. In this studio, in which he spent nearly all his time, Erwin Speckter acquired his first instruction in art, and his natural taste rapidly developed itself. In 1820 his father, the banker, at the instance of the Herrich erected a lithographic press, the first which was established in North Germany, and young Speckter made some attempts in portraits, and in drawings to illustrate the old Heinrich Fuchs who died in the Father's house.

In 1828 Von Rumohr returned to Hamburg from his second visit to Italy, and, being struck with admiration of the promising talents of Speckter, urged him on in his career, and particularly to study the monuments of art in and about the neighbourhood. This led to an artistic tour which he performed in 1828, with a brother and another artist friend, through Schleswig and the neighbouring country. The chief objects of this journey were the cast altarpiece of Hans Brügman at Schleswig (lithographed by Böndel) and the picture of Maeling at Liibeck, the latter of which Speckter and his brother Otto published in lithography. These early works gave Speckter the peculiar bias which at that time characterised the majority of the younger artists of Germany, and the arrival of Overbeck's picture of Christ's Entry into Jerusalem, for the Marien Kirche of Liibeck, confirmed this tendency, and for a time enlisted Speckter among the young enthusiasts who appear to be devoted to the restoration of the sentimental symmetrical art of the Renaissance in Germany, with the addition of academic drawing. Overbeck's picture has been lithographed by Speckter, and at this time Speckter's chief labours were indiscriminate studies from nature of every description, and portraits: his first oil-picture was a view of the town-house of Möllin. His adoration of Overbeck's pictures has been to have himself a species of awe from attempting such high subjects himself; he was also always guided in his studies by Rumohr.
In 1825 he visited Munich, and placed himself under the direction of Cornelius, who expressed great admiration for his ability; and, after the completion of his cartoon of the Resurrection of Lazarus, allotted him one of the vaults or loggia in the Munich church, where he was painted. A fresco with incidents from the lives of the greatest modern painters. Cornelius selected Fra Giovanni da Fiesole for Speckter, as peculiarly suited to his taste. Speckter, then already possessed of a sufficient score of commissaires, was naturally exultation, but he did not live to execute it, for the Pinacoteca was not ready for the frescoes until many years after this date.

In 1827 Speckter returned to Hamburg, chiefly to be in the vicinity of the above-mentioned work by Overbeck, while he painted his picture of Christ and the Woman of Samaria; but the deep impression made upon him by Overbeck's picture had a very prejudicial effect upon him, through his inordinate admiration for his pictures, and his inordinate desire for being the greatest painter of his day. He went to Italy while the work was being completed, and had hitherto possessed him, though it was gradually yielding to his own experience, was finally subjected by the contemplation of the great Italian works in the Museums of Berlin and Paris, and especially those of Filippo Lippi, Raphael, and the greatest Venetian masters.

Speckter arrived in Rome in January, 1831, after a short stay at Venice, from which is dated the first of his very interesting letters sent from Italy, which have been published by Dr. Rummohr, frequently reprints of them. In Rome, Speckter and Naples, until the summer of 1834, when he was called to Hamburg to paint in front of the villa of Dr. A. de Chatouven, near the Villa de Popoli. In Rome Speckter confided his labours almost exclusively to studies, and these are in the general spirit of Italian art, and quite a different style from his early efforts. The only oil-paintings he painted in Rome were two of Albanian women, in ideal characters, and a large picture of Samaon and Dalillah, which was purchased by Rummohr.

In the spring of 1836, though suffering greatly from asthma, Speckter commenced his frescoes; he had in the interval completed three of the principal cartoons: the objects are from Greek mythology, and the figures are half the size of life. These objects were—1. The winged Pegasus from the Muses, and the Hippocrene fountain, which springs from the horse (M. de Chatouven describes the nymphs or goddesses of this place as the Genius guardian of the place). 2. Two Greek columns; 3. The Graces, in a grove of laurels, decorate the bow and quiver of Cupid, and offer him a cup of ambrosial drink; and 5. The Fates, lulled by the lyre of Cupid, have ceased their labours, and recline on cushions; the distance is concealed by a curtain. The first of these designs, distinguished for the exquisite beauty of its forms, was completed in fresco, and the second was partly executed; the third was not commenced. His weak state forced Speckter to leave his work at the beginning of November, and he died on the 30th of that month in 1832, deeply lamented by his friends, and by none more than Rummohr, who wrote a short account of the character, which is incorporated in the notice of him which precedes his letters. These letters, published in 1846, under the title of 'Letters of a German Artist from Italy' ('Briefe eines Deutschen Künstlers aus Italien'), Leipzig, 1846, are all of historic matter and reflections on art. Speckter's whole career is a remarkable instance of the power of nature over convention, where the love of art was real. The essential attractions of art lie in the harmonies from conventional and systematic, in which art was only secondary to a peculiar sentiment independent of it, to the art itself, and for its own sake. Speckter's transition from convention to nature is not singular in the history of German art. (Briefs, already mentioned.)

SPECTRUM, in optics, is a name applied to the elongated image of the sun which is formed on a screen in a darkened room when a slender beam of the sun's rays passing through a perforation in the wall or in a window-shutter has been afterwards transmitted through a prism formed of any transparent medium (Diazoros, P. C.; and, for the dark lines observed, Babinet and V. C.).

If a prism of crown-glass, and one of flint-glass, have their refracting angles of such magnitudes that the spectrum formed by one shall be of the same length as that which is formed by the other, and that if the one prism is in the direct rays, the other in the reflected, the rays will not be wholly converted, and some colour will still remain in the image formed on the screen which receives the refracted pencil. This circumstance was first observed by M. Clairaut; and the coloured image was called by Dr. Blair a secondary spectrum.

When a spectrum is formed by a prism of crown-glass, the mean refracted ray meets the screen at the boundary-line between the blue and green spaces; but if a spectrum of equal length is formed by a prism of flint-glass, the mean ray, instead of being at that boundary, will be much nearer the red or least refracted end of the spectrum; consequently, with flint-glass, the rays which suffer the least refraction occupy a greater length in the spectrum formed with a prism of crown-glass, so that the least refrangible rays occupy a greater, and the most refrangible rays a less extent than they respectively occupy in the spectrum formed by the latter prism. The pencil of white light be made to pass through two prisms, one of crown and the other of flint-glass, their refracting angles being such that the red and violet rays of the spectrum are unaltered, there will be formed on the screen a double or secondary spectrum, its upper part, or that which is near the violet end, consisting of the green light which remains unaltered, and the lower part consisting of the light formed by the unaltered red and violet rays, the image of the upper part will appear to be fringed with green and the lower side with a purple tint arising from the blending of the red and violet rays.

But if a pencil of white light be made to pass through two prisms, one of crown-glass and the other of rock-crystal, their refracting angles being such that the red and violet rays of the first spectrum are united, there will be formed a secondary spectrum in which the lower part is green and the upper part purple; or, if the bar of a window-frame be viewed, the upper part will appear to be fringed with green and the upper with purple.

This dispersion of light, which remains after the rays have been refracted through an object-glass composed of two lenses, of which a greater than an equal thickness is formed by a combination of their angles, is due to the incompleteness of the achromatic telescopes: the fact of the dispersion will be evident in any such telescope if the eye-pieces be drawn out beyond the point at which a luminous object as the moon appears distinct, or be placed nearer the object-glass than that point; for, in the former case, the object will appear to be surrounded by a bright margin of green light, and, in the other, it will be surrounded by a fringe of purple light. (Breuer, Treatise on New Philosophical Instruments, p. 306.)

Prisms of three different media might be formed which would unite the rays of three different colours; but the incorrect disposition of the light and the biographies of the colours formed, which is incorrect for the biographies of the colours formed, which is incorrect for that which remains when two differently coloured rays are united, and Sir John Herschel, in the 'Encyclopaedia Metropolitana' (art. Light, No. 446), proposes to call it a tertiary spectrum. The greater skill of higher orders might be found by using a greater number of prisms, for the purpose of uniting with the former the rays of other colours; but the diminution of light caused by the employment of so many media would become an evil greater than that which is proposed to correct. Sir David Brewster has given the name of tertiary spectra to the images formed by the incorrect colours which remain when two differently coloured and violet rays are united by casting a pen of white light to pass through two prisms of the same medium, as flint-glass, with their refracting angles in opposite positions: in this combination the refracting angle of one
prism is greater than that of the other, and the pencil of light is a little the brighter in the fall of the sun. This produced such obliquity to the surface as to render the dispersion of the red and violet rays in that prism sufficient to allow it to be exactly corrected by the contrary dispersion produced by the other. Again, a planchet proposes to call spectra so produced subordinate spectra.

The celebrated Fraunhofer first observed that when a beam of light from the sun, after passing through a narrow slit (less than a line in breadth) in the window of a darkened room, and then through a still narrower aperture in an opaque screen placed a few inches from the object-glass of a telescope (the two apertures being parallel to one another), was also observed, there resulted a number of colored fringes produced by the diffraction of light at the edges of the aperture, being viewed through the telescope, assumed the appearance of spectra similar to those produced by the refraction of light through a prism of some transparent medium. To these images Fraunhofer gave the name of spectra of the first class; they are composed of variously coloured light, the tints melting into one another by insensible gradations, and they exhibit dark lines as in the usual prismatic spectra.

When there was placed before the telescope a grating consisting of many very slender wires parallel to one another and to the aperture in the wall, and having very narrow intervals between them, this screen produced a series of colored spaces on either side of the image of the aperture in the wall, and beyond this, on each side, a series of spectra each consisting of variously colored spaces, of homogeneous light, separated from one another by dark lines; these he called spectra of the second class.

When two linear apertures only were made in the screen at the object end of the telescope, there appeared in the field, between the image of the aperture in the wall and the first of the spectra, on each side, what Fraunhofer designated imperfect spectra of the second class; these consisted ofcoloured spaces similar to those in the spectra of the first class, but without the dark lines; and these linear apertures only were formed in the screen, there appeared, between the image of the aperture and the nearest imperfect spectrum of the second class, other spectra less distinctly formed than the last. Fraunhofer lighted upon the third class of spectra, composed of colored spaces, of homogeneous light, and separated from one another by dark lines; these he called spectra of the second class.

Several beautiful varieties of spectra were observed by Fraunhofer when the light was transmitted through three or a greater number of small circular apertures in a metal plate, and also through two frames, each carrying a number of slender wires parallel to one another; the frames being placed so that the wires in one were at right angles to those in the other.

SPECLARIA (so called from Speculum Veneris, Venus's mirror) is a genus of plants belonging to the natural order Campanulaceae. It has a rote corolla, a linear-oblong prismatic capsule opening by lateral pores between the calyce segments. In other members of the genus the corolla is always shorter than the ovary. This plant is a native of the corn-fields of Great Britain, and is found commonly throughout the region of the Mediterranean. There are several other species of this genus, all of which are worth cultivating on account of their showy flowers. The seeds should be sown in the open ground, where it is intended the plants should remain. By sowing the seeds in the autumn an early blossoming may be expected in the following summer, and by successive sowings in the spring and summer they may be made to blossom for several months during the summer.

(Don, Gardener's Dictionary ; Babington, Manual of British Botany.)

JOHN CHARLES SPENCER, THIRD EARL, will be best remembered by the title of courtesy, Viscount Althorp, which he bore from his birth, through, it may be said, the whole of his public life, and until within a few years of his death. He was the eldest son of George John, second Earl Spencer, and Lavina, eldest daughter of Charles Bligh, first Earl of Lucan, and was born on the 30th of May, 1750. Like his father, he was fond of music, for his love of literature and his munificent expenditure in the collecting of rare books, he was educated at Eton; whence he was sent to Trinity College, Cambridge, where he took the honors of A. B. in 1771.

In April or May, 1804, towards the close of the second session of the second Imperial Parliament, Viscount Althorp entered the House of Commons as one of the members for Cloudesley, and took the honours of M. A. in 1771.

On the 11th of February, 1806, on the formation of the Whig ministry of Mr. Fox and Lord Grenville, in which his father Earl Spencer, took office as Secretary of State for the Home Department, Lord Althorp was appointed one of the Junior Lords of the Treasury; and this appointment having vacated his seat, he offered himself for the University of Cambridge, which had been represented by the late premier, Mr. Pitt, the other candidates being Lord Henry Petty (now Marquess of Lansdowne), who was the new Chancellor of the Exchequer, and the present Lord Palmerston. The votes were, for Lord Henry Petty 331, for Lord Althorp 125, for Lord Palmerston 128.

To the next parliament, which met in December, 1806, Lord Althorp was returned at the head of the poll for the county of Northumberland, and held his seat six years. It was, for his lordship, 2095; for the other member, William Ralph Cartwright, Esq., 1990; for Sir William Langham, Bart. (the defeated candidate), 1381. After this his lordship continued to be returned for Northumberland for the next session, and was again returned. He was an ardent supporter of the opposition: he was, in 1820, placed on the ill-fated down to the passing of the Reform Bill. In the first Reformed Parliament, which met in January, 1828, he sat as one of the members for the southern division of that county.

Lord Althorp, of course, lost his seat at the Reform Act, and when the Grenville administration was dissolved in March, 1807; nor did he again hold office till the accession of Lord Grey and his friends to power in November, 1830. During all this interval, although he did not come forward in debate so frequently as some other members, he was regarded as one of the steadfast supporters of the Opposition in the House of Commons; and, while he was making his way to the highest place in the confidence of his party, it is said he declared that there was no man on either side of the House who the public generally held in greater respect for his universally admitted patriotism and freedom from the narrowness and rancour of faction. Yet he was no temporizer or half-and-half politician. On all the great questions of the day he took a decided part; and on most of the occasions on which his party made a stand against the government, he went as far as he could with them as any man. In 1817, for instance, we find him supporting an address to the throne for a reduction of the number of the Lords of the Admiralty, and opposing the suspension of the Habeas Corpus Act, the maintenance of so many permanent officers by the state, the abolition of the Alien Act, and the additional grant to the Royal Debt; in 1819 moving for an inquiry into the State of the Nation; in 1823 moving for a repeal of the Foreign Enlistment Bill, and opposing the measure; in 1824 moving for a Committee of Inquiry into the general state of Ireland; in 1825 opposing the Suppression of the Catholic Association; in 1826 moving the first reading of the bill to repeal the Test and Corporation Acts, and opposing the grant of 2000l. per annum to the family of the late Mr. Canning.

Lord Althorp was also prominent for several years, about this period, in a series of economical attacks upon the Tory administration, and his house was the resort of a powerful section of the Whig party, who considered him their leader in the House of Commons. There were few questions of public importance, over and above those already mentioned, in which he did not take a practical and useful share; and his sound judgment, under all the vicissitudes and excitement of Parliamentary affairs, amply justified the confidence and attachment which he was regarded by the party. There was about him, indeed, so much reality of purpose, such unostentatious manners, a bearing and simplicity so characteristic of the English nation, that a few sentences from him were equivalent to a strong confirmation from some of his countrymen; and though he was not fortunate enough on all occasions to escape censure, we believe it may be truly said that such censure generally emanated from individuals whose views had been frustrated, and whose plans had been thwarted, and he left politics, he was not less in charity with all men than they

Vol. II.—4 D
were in charity with him. "Honest Lord Althorp" was the current phrase by which his Lordship was recognised by the House of Commons and the public for many years.

The House, it is true, has been often led by what are called able men, and the Whig party in particular has never been wanting any more than it was during his leadership, in distinguished talents and rare oratorical ability. We doubt however whether amongst the many distinguished persons who formed Lord Grey's administration, a single individual could have been selected who would have combined in the support of the great measures of the day so much popular confidence and support, and would have carried them through parliament with unexampled ease and an earnest equality to Lord Althorp. To the honour of the House of Commons, character in public men has an authority there which stands its possessor in lieu of more striking qualities; and no distinguished age need be ashamed, on being reminded of the great orators of the last generation, that for several years the public business was conducted by a gentleman whose language was as plain as his appearance, but who stood without equal in the country. It is a fact which he had no object but the prosperity and prosperity of his country.

In respect to the great questions which have risen into political discussion and excited so vital an influence for the last four years on the legislation and statements of the day, we mean those connected with the emancipation of trade and commerce, we have reason to know that Lord Spencer warmly sympathised with the principles of the noble and candid gentleman, and there is no doubt that his influence and support would have been given to the policy and measures of 1846.

It will be remembered that upon the address to the crown in the House of Lords in August, 1837, when the Whig budget and the stability of Lord Melborne's government were at issue, he moved the address on that occasion, and emphatically declared himself in favour of free trade. There was an occasion also, when a sudden shock of his death, when he lost the confidence of a portion of his agricultural friends by an open declaration in favour of a total repeal of the corn laws; and we question whether Mr. Cobden ever made greater progress amongst the middle or the upper classes of society than when he could appeal to the revised sentiments of so devoted and so distinguished a farmer as Lord Spencer.

But to return to the narrative: In November, 1837, the Whig section of the Goderich cabinet fixed upon Lord Althorp to be chairman of a Committee of the House of Commons, which it was proposed to appoint to take into consideration the general state of the national finances, and the premier (the present Earl of Ripon) appears to have given a qualitative pledge that Althorp would be respectively appointed, after a communication had been made to Lord Althorp, and his lordship had signified his conditional acceptance of the introduction of the bill by the opposition. Mr. Herries, the chancellor of the Exchequer, this affair led to the resignation of their offices both by Mr. Herries, and Mr. Huskisson, secretary for the colonies, and to the breaking up of the administration on the 8th of January, 1838. For full details the reader is referred to the "Annual Register" for 1839, pp. 9-12.

On the accession to the power of the Grey administration in November, 1839, Lord Althorp was appointed chancellor of the Exchequer. His position, and the sound ability which he evinced in the management of great political and economical questions, with the universal confidence in his integrity, made him the ministerial leader in the House of Commons. No man probably ever filled the latter post with less stress of both measures in all their details, the readiness and accuracy of his recollection, and even the talent of exposition and advocacy which he displayed, produced a general conviction that whatever lordship he had been enabled to look into all considerations, have been placed in better hands.

The appointment of Lord Althorp to a high ministerial office in the House of Commons was attended with the serious drawback, that his father, Earl Spencer, having already attained to the age of seventy-two, Lord Althorp was very liable to be soon and suddenly called away both from the House of Commons and from his office, which could only be held by a member of that House. In point of fact, the death of Lord Spencer in the latter part of 1844, by occasioning this change, broke up the ministry. [William IV.] When the administration of Sir Robert Peel and the Duke of Wellington, which succeeded, was obliged to resign in April following, and the Whigs came again into power under the premiership of Lord Melbourne, Lord Althorp, now Earl Spencer, was, as well as Lord Brougham, left out of the new cabinet. It was understood that he declined to take office, and indeed that he had reluctantly been induced to resume the Chancellorship of the Exchequer after giving in his resignation when Lord Grey finally retired in July of the preceding year. There can be no doubt that in losing him, the remnants of the original Reform party, now deprived also of Lord Durham, Lord Stanley, Sir James Graham, Lord Ripon, the Duke of Richmond, Lord Carlisle, Earl Grey, and Lord Brougham, lost one of its chief stays. He was succeeded by Lord Palmerston, Mr. Grant (now Lord Glenelg), Lord Auckland, Lord Holland, and Lord John Russell still remained.

What is said of Lord Althorp by the writer of the Memoir in the ' Gentleman's Magazine' is the more valuable as the testimony of a political opponent:—"His sincerity was never doubted, nor the integrity of his motives. . . . Up to the hour of his departure, his quitting of public life, and the execution of the measures of the House, if he did not support his population; and no minister ever retired into private life accompanied with warmer wishes for his happiness, or a more general feeling of good will."

Earl Spencer had always been strongly attached to agricultural pursuits; and now that he was not only relieved from official occupation, but had nearly withdrawn altogether from politics and public life, both by the government, with more eagerness than ever to promote farming, the rearing of cattle, the patronage of agricultural associations, and whatever promised to advance his favourite science. "Regardless of expense and of personal inconvenience," says the author, "we have just quoted, he was always to be found to advocate and support at all the great agricultural meetings throughout the country. Indeed he may be said to have been the father of many, as he certainly was the patron of all. He was for many years President of the Smithfield Club; and, in the year 1837, in the course of his address to its members, he suggested the formation of the Royal Agricultural Society. . . ." Earl Spencer was the first President of this Society in 1839-40, when the meeting took place at Southampton. In the formation and operations of the Yorkshire Agricultural Society he also connected himself. He less prominently, but still marked by zeal than by a sound discrimination. His Lordship was President of the Yorkshire Society when its meeting was held at Doncaster in 1843."

Lord Althorp was one of the official members of the Boxhurghe Club (for the reprinting of rare and curious tracts), of which his father was the first President. He was also Vice-Chairman of the Council of the Society for the Diffusion of Useful Knowledge; and he was a liberal contributor to the fund raised for the 'Biographical Dictionary' which the Society commenced. Lord Brougham dedicated to him his 'Discourse on Natural Theology,' published in 1855, in an address in which he says, 'I impute the fruits of those studies to you, because you were the inquirer in those inquiries—are beyond most men sensible of their importance—on the general in the opinions which I profess to maintain—and had ever formed the design of giving to the world your thoughts upon the subject, as I hope and trust you now will be moved to do all the more for the present address. Lord Brougham's 'Dialogues on Instinct,' first published in his Supplement to Paley's Natural Theology,' in 1844, are also supposed to be carried on with much of your time in these inquiries; the study of which much of his leisure is always consumed."

Lord Spencer died at his seat of Wiseton Hall, in Nottinghamshire, on the 1st of October, 1845. He had married, on the 14th of April, 1814, Esther, only daughter of Richard Bourchier, 2nd. Se., of Wiseton; he also died on the 11th of June, 1818, without issue; and his lordship succeeded in
the present by his next surviving brother, Frederick, now Earl Spencer.

20th February, 1846.

Conchifera, from the Cretaceous system of Kent. (Sowerby.)

Sphenacanthus, a fossil genus from the Coal formation of Scotland. (Agassiz.)

Sphenochinus, a genus of fossil fishes from the lins and walden series of England. (Agassiz.)

Sphenophyllum, a fossil genus of plants from the coal formations of Europe and North America. (Brongniart.)

Sphenodon, a genus of fossil fishes from the London clay. (Agassiz.)

Spider, [Arachnida, P. C. J. The habits of spiders have recently formed the subject of an interesting and valuable report drawn up at the request of the Linnean society of London for the Advancement of Science, by Mr. Blackwall. This report, which is printed in the Transactions of that body for 1844, is full of new and curious matter. It touches on many points in the economy of spiders hitherto, it is said, unobserved and unimproved. For instance, it seems to demonstrate the possibility of the possession of any useful, valuable memoirs on the same subject in the later volumes of the Linnean Transactions, and several papers on new forms in the 'Annals of Natural History,' by Mr. Adam White, also an important and elaborate account of the anatomy of some species by Mr. Tulk.

Of the discoveries of Mr. Blackwall the most interesting and extraordinary relate to the sexual intercourse of these animals, and to the purposes served by their palp in aiding in the continuation of the species. The facts made known on this subject are among the most singular discoveries of late years. For them we must refer to the report mentioned. We shall quote on a passage respecting the reproduction of the amputated palp—

'When the palp of male spiders which had been amputated before the penultimate moults are reproduced, the sexual organs, perfect in structure, are reproduced also. (See experiments 8, 10, 11, 14.) Unexceptionable evidence in support of this singular fact is to be found in their reduced dimensions and integrity of form; but it will scarcely be denied that the other males of the same species preserved their detached palp. That the function of the sexual organs is not in the least affected by their reproduction there exists the most satisfactory proof. In the last of those experiments, he notes, the palp was re-grown, while a part of the sexual organs in male spiders, recorded in this report, the male Tegenaria civilis, stated to have possessed the right palpus only when introduced to the female, is identical with the condition of the experiment 8 in the foregoing series; consequently its sexual organs had been reproduced, yet the fertility of its mate bore ample testimony to the unimpaired efficiency of its generative agency.'

Mr. Blackwall adds some very curious facts respecting the reproduction of spiders' limbs generally:

'Physiologists, in conducting researches relative to the reproduction of the limbs of spiders, seem to have limited their investigations to the legs of these animals; whereas in the experiments detailed above, the palpi and spinners, as well as the legs, were operated on; and all these parts are found to be renewed, and afterwards to have their dimensions enlarged at the period of molting only; it appears also, that if a part of a limb be amputated, as the tarsus of a leg or the digital joint of a palpus, the whole is reproduced, all the joints of the new limb, though small, being proportionate to those of the corresponding limb on the opposite side, with the exception of the digital joint of the palp of male spiders when the sexual organs are not reproduced, which is usually somewhat modified in size and form by that circumstance."

11. The following facts, occasionally presented by spiders, are of no small consequence in their bearing on specific determinations—

1. Variations in the colour and size of spiders of the same kind, resulting from differences in age, sex, food, climate, and other conditions of a less obvious character, as they conduct

largely to the introduction of Sestigous species, have long engaged the attention of arachnologists, while those arising from extraordinary organic modifications, in consequence perhaps of their less frequent occurrence, have been almost entirely overlooked. The former class of variations in the latter description possess, in relation to physiology and systematic arrangement, will be best illustrated by a few examples.

1. A supernumerary eye, situated between the two small ones constituting the posterior intermediate pair, has been observed in an adult female Theridion filipes. The total number of eyes possessed by this individual was nine, and their arrangement symmetrical.

2. An immovable female (Thomisus cristatus) had the two lateral pairs of eyes only; the four small intermediate were altogether wanting, not the slightest rudiment of them being perceptible even with the aid of a powerful magnifier.

3. A short but perfectly formed supernumerary tarsus, connected with the base of the tarsal joint of the right posterior leg on its outer side, has been noticed in an adult female Lycosa caesarea.

4. Deficiency of the right intermediate eye of the anterior row has been remarked in an adult male Lycosa carbonica.

5. The left intermediate eye of the posterior row was perceived to be wanting in an adult female Epeira setacea, and the right intermediate was not brought to its usual size.

6. An adult female Cupiolo auro was found to be without the left intermediate eye of the posterior row.

7. The right intermediate eye of the posterior row in an adult female Epeira setacea had not one-eighth of the natural size, being altogether wanting.

SPIKERNARD. [Nardostachys, P. C. S.]

Splanthus (from σπλάνθος, a spot, and ὀδός, a flower, because of its dotted or speckled flowers), a genus of plants belonging to the natural order Compositae and to the suborder Cynorrhynchia. It has a many-flowered head, either heterogamous with the florets of the ray ligulate, or homogamous with all the florets tubular and 5-toothed; the involucres is in two rows, appressed, shorter than the disk, the outer scales somewhat leafy, the inner rather membranous and folded up.

S. obovata has a branched diffuse stem, opposite stalked broadly ovate leaves, obvolute at the base, truncate or somewhat cordate. The pedicels are one-headed, longer than the leaf. The heads thick, ovate, and discoidal. The achene eliptical at the angles, bi-arristed or awoless. The whole plant, but especially the involucre and receptacle, acts as a powerful stimulant of the salivary organs.

(Lindley, Flora Medicinal.)

SPINELLI, PARRI, a celebrated old Italian painter, was the son of a Venetian artist, and was born at Ancona apparently about 1388-90, though his father was then very old, upwards of seventy. This conjecture however rests only upon Vassari's statement respecting the age of Spinelio, and upon the assertion that for their parents died three years and a half before the date of the birth of Mr. Parr. His birth is given as in 1444, which is on the altar-piece of San Cristofano at Arezzo, which is attributed to him.

He was first instructed by his father, and was afterwards employed by Lorenzo Ghiberti, and afterwards by Benvenuto Cellini, who was involved in the preparation of the celebrated gates of the Baptistry of San Giovanni, which were executed between 1402 and 1484. He painted chiefly in Arezzo, and Vassari enumerates many of his works, but few now exist. He returned to Ancona, says Vassari, upon the death of his father, and after many years' absence, from which it would appear that the father lived further in the fifteenth century than is at present supposed: he is known to have been living in 1498, and his death is supposed to have happened about this time. Vassari's statement that he died in 1440 is probably a mistake as well as an error, as the account of Parr's assisting Ghiberti and returning to Arezzo at the time of his father's death and after many years' absence, is a complete contradiction to it.

Parr was an excellent colourist, and was the best practical fresco painter of his time; his draperies were also good, but his figures were too long in proportion; Vassari says some of them measured as many as eleven heads in height, and yet they were not ungraceful.

[Vassari, Vite de' Pitteri, &c.]

SPIRITUAL COURTS. [BENCHEMICAL COURTS, P. C. S.]

412
SPIROGLYPHUS, a genus of fossils from the mountain Jæstsmen of Iceland. (Mc-Coy.)

SPIRIFORA. [Cascoara, P. C. S.]

SQUALORIA, a genus of fossil fishes from the Five of Dorset, (Riley.)

SQUARCIONE, FRANCESCO. This painter, celebrated for his superior acquirements as well as his great school and rich collections of works of art, was born of a good family at Padua, in 1584, and after living in Greece and Italy, lived there in great affluence and distinction till his death in 1744. His house was one of the chief attractions in Padua. He was the master of Andrea Mantegna, who lived some time in Squarcione’s house. From his very numerous school (he had 137 scholars) he was called the father and primo maestro of painters. He appears to have been more engaged in teaching than in practising the art. (VENETIAN SCHOOL OF PAINTING, P. C., vol. xxii., p. 212.) Vasari terms him erroneously Jacopo Squarcione. (Ridlisl, Vite de’ Pittori Veneti, etc.)

SQUATIINA, a genus of cartilaginous fishes, of which the Fish of the name is formed from all the other sharks in the position of the mouth, which is closed at the extremity of the snout; and not placed below, in position of the eyes, which, instead of being on the sides of the face, are in the form of the flattened head. The body is very broad and flattened horizontally; the head is round. The dorsal fins are placed farther back than the ventrals, and there is no anal fin present.

STADE DUTIES are so called from Stade, in the kingdom of Hanover, a town situated on the right bank of the Schwinge, three or four miles from where it falls into the Elbe, and 22 miles west by north from the city of Hamburg. The name Brunsbaison Zoll is commonly used for, from the village of Brunsbaison, at the mouth of the Schwinge, where there is a customs-house and a royal guard-ship, and where the duties are collected that are levied on vessels and merchandise passing up the Elbe. The original duties, which were regulated by a treaty made in 1691, were light, but were gradually increased by the Hanoverian government till they amounted to about 40,000l. a-year. The duties levied were about 5% per cent. on all imports, more on some articles and less on others. British vessels by a proclamation of Geo. II., December 1, 1736, were allowed under certain regulations to sail directly up to Hamburg, without coming to anchor at the mouth of the Schwinge, as other foreign vessels were obliged to do.

By a convention between the King of Hanover and the other Elbe-bordering states (Emperor of Austria, King of Prussia, King of Denmark, Duke of Mecklenburg-Schwerin, Duke of Anhalt-Cotzba, Duke of Anhalt-Dessau, Duke of Anhals-Bernburg, Free and Hanseatic town of Liibeck, and Free and Hanseatic town of Hamburg), dated April 15, 1844, in conformity with articles 108 and 116 of Act of Congress of Vienna, of June 9, 1815, the Brunsbaison Tolls were revised, regulated, and settled according to the convention, as agreed upon by the contracting parties.

By a treaty of commerce and navigation between the Queen of England and the King of Hanover, signed at London, July 22, 1844, British and Hanoverian vessels arriving at the Hanoverian ports, or at other ports on the Elbe, not being vessels of either country, are mutually subject to no other or higher duties or charges than those which are now or shall hereafter be imposed upon the national vessels of the two countries on their arrival at, remaining in, or departure from such ports. All articles of the growth, produce, or manufacture of Great Britain or Hanover, which are or shall be permitted to be exported or imported in British or Hanoverian vessels, are mutually free of all such duties or charges.

The vessels of either country, and no distinctions of duties or drawbacks shall be made. By article 6, 'From and after the 1st day of October, 1845, no other or higher duties or tolls shall be levied, as regards the tolls or charges known by the name of the State or Brunsbaison tolls and charges, on British vessels passing up the Elbe to the point where the tolls of the Upper Elbe commence (that is to say, up to and including the town of Hamburg), or upon the cargoes of such vessels, than the tolls and duties which are specified in the convention between the Elbe-bordering states, which was signed at Dresden on the 13th of April, 1844, and in the separate articles, regulations, and declarations to the said treaty, in so far, however, to the following articles of British produce and manufacture (that is to say, yarn, thread, manufactures of cotton, wool, and linen, tin and tin plates, articles of iron and steel, iron pipes, wrought iron, cast iron, brass, copper, and similar alloys of metals and manufactures thereof), it is agreed that the duty or toll to be levied, whether in British vessels or in vessels of any of the Elbe-bordering states, shall be no other than, or in excess of, the duty or toll specified in the said articles. The treaty is to continue in force till January 1, 1844.

STANLEY, ST. LEONARD is a town and village, formerly a market-town (and described as still being one in the Article Gloucestershire, P. C.), in the lower division of Whiston hundred, in the county of Gloucester, about 3 or 4 miles W.S.W. of the town of Stroud, and about 12 miles by W. of Gloucester. The adjective to its name, St. Leonard, serves to distinguish it from two other Stanleys in the county, namely, the adjacent parish of King’s Stanley and the parish of St. Leonard, both near Winchcombe, in the same county. The area of the parish is 910 acres; the population at the different enumerations was as follows:—1801, 690; 1811, 638; 1821, 757; 1831, 649; 1841, 684. The number of inhabited inhabited and 19 uninhabited. There were none building. The village consists of three or four small streets meeting at the church, which is dedicated to St. Swithin, and is an
STANZIONI, M'ASSIMO, Cavalieri, a celebrated Italian architect, was the pupil of Carlo Fontana. He has long had a fame as one of the first architects of his time. His works, as the Mascherina, Palazzo Molini, etc., in Venice, show a happy union of the antique and modern, of simplicity and elegance. He died in 1760.

(Parliamentary Papers; Ordinance Map; Forthroy's Gloucestershire.)

ANTHEMION, or the anthemion, is a plant belonging to the family of the Boraginaceae, and is found in the Mediterranean region. It is a perennial herb, with alternate, oblong, serrate leaves, and small, white, bell-shaped flowers. The calyx is tubular, five-lobed, and the corolla is white or pink, with five petals. The fruit is a capsule, containing many seeds.

S. saxatilis has spathulate leaves narrowed into a flat stalk, the calyx segments blunt, entire, and without intermediate teeth.

S. reticulata has spathulate leaves narrowed into a flat stalk, the calyx segments acute, denticulate. It is found in muddy salt marshes in Norfolk and Suffolk.

(Bahington, Manual of British Botany; Lindley, Vegetable Kingdom.)

STATUTE (Scotland). It would be difficult to explain the character of the old legislation of Scotland, the method in which it was sanctioned, or the constitution of the parliaments by which it was passed. All the light that probably is to be obtained on the early history of the statute-law has lately been embodied by Mr. Innes, in his preface to the edition of the "Scottish Statutes and Old Laws," published by the Record Commission. 'Whatever,' he says, 'may be the case in other countries, it is not easy in Scotland to distinguish the ancient legislative court or council of the sovereign from that which discharged the duty of counselling the king in judicial proceedings. The early lawyers, indeed, enacted statutes by the advice of the bishops, earls, thanes, and whole community, or through the common council of the Kynys; but during the reigns previous to Alexander III., we find the king also deciding causes in a similar assembly of magnates: while laws of the greatest importance, and affecting the interests of the whole nation, have been sanctioned by the king and "his judges." It is probable that the proceedings of the assembly, legislative or judicial, of the principal barons, though irregular, was in general an imitation of the parliament of England. Before the middle of the fourteenth century the lands of the southern districts of Scotland had been in a great measure partitioned among Norman adventurers, some of whom owed a double allegiance to the crown both of England and Scotland; and it was probably for the sake of better for them with the practices and opinions of the country with which they were earliest connected. A large proportion of the lowland population of Scotland were at the same time Saxons refugee from England. So early as the reign of David I. (1124) we begin to find that the municipal corporations had a voice in the ratification of the laws. 'The parliament,' says Mr. Innes, 'assembled by John Balliol at Soone, on the 9th of February, 1292, was probably the first of the national councils of Scotland which bore that name in the country at the time, although later historians have bestowed it freely on all assemblies of a legislative character. We have no reason to believe that any change in its constitution occasioned the adoption of the new term, which soon became in Scotland, as in England, the received designation of the great legislative council solemnly assembled. It was not till a few years later, on occasion of the parliament of Dunfermline, that the first in Scotland was probably at the desire of the French king, procured the treaty to be ratified, not only by the prelates, earls, and barons, but by certain of the barons of his kingdom. That treaty was finally ratified by the king at Dunfermline, 1295, and the seals of six barons were then affixed to the deed, and with those of four bishops, four monasteries, four earls, and eleven barons. Notwithstanding this very formal ratification, however, it may be doubted, both from the peculiar phraseology of the deed itself, and from the silence of historians as to any meeting of a parliamentary nature in which it could have been voted, whether the parties stated as consenting, and especially whether representatives of those six barons, were actually present in a national assembly of parliament. The acts which were thus sanctioned—sometimes, perhaps, by the separate adhesion of the principal interests of the country, sometimes by assemblies—were of a mixed character. Some were judgments in particular disputes, and were accompanied probably by the announcement of a principle on which such questions should thenceforth be decided; others were acts of executive authority: and others might be regulations having the character of fixed and general laws. The proceedings related to matters of private right, the recording instrument would be put into the hands of the party interested. When the proceedings of the national council, says the authority already cited, 'related to matters of a more public nature, such as negotiations with foreign states, its earliest records were probably of a similar kind, and consisted of letters or other communications which embodied the results of its deliberations. Perhaps the earliest instances of this kind that now remain are those important deeds of the reign of Alexander III.; when, however, a more
artificial system must have been beginning to prevail. It would be still more interesting to ascertain the modes in which the more general ordinances and laws of the realm were enacted and recorded; but on this head the loss of every original document is vivid, and the attempt to collate the results from the mutilated and imperfect transcripts of a later age, and from the analogy of the other states of Europe, it would appear that the more important and general statutes were framed into more capillars, and impressed into a writ, addressed, in the name of the king, to the chief ministers of the law in the different districts of the kingdom, requiring the publication and observance of them. The laws of the burghs, the acts of David I., the acts of the Parliaments, and the ordinances of Alexander II., as found in the old manuscript collections of lawyers, seem to be the fragments of various capitals of this kind. The acts of David I., 'Assist Regis David,' are reported to be the oldest fragments of legislation in Scotland, and are partly, but not entirely, traceable to so early a period as the reign of the king with whose name they are associated. The burghal laws, 'Leges Quattor Burhorum,' constitute the oldest systematic collection of laws. They too may be referred to the reign of David, and though historians give him the credit of having planned the whole system of the municipal corporations, it is more likely that this code of laws was formed by his troubles and difficulties, which had previously come into existence with the growing influence of the burghs. The coincidence between these early vestiges of Scottish legislation and the old law of England is remarkable. Burghs in Scotland and in the burghs of the technical phraseology is frequently used, which still belongs to the law and practice of England, but has long been discarded in Scotland. Indeed, it is very clear that, before the attempt of Edward I. to rule the realm, there was a harmony in the law and spirit between the two nations, and that Scotland generally followed or accompanied England in all her constitutional progress. There is still a more remarkable coincidence of English law with English legislation. English Justices, or officers of the general code of the old laws of Scotland. It was, like the fragments mentioned above, attributed to David I., who had obtained the character of the Justiciar of Scotland; but it is undoubtedly a part of the English law in the sixteenth and seventeenth centuries it was very popular, as an understood national code; but it was subsequently discovered to have many features in common with the compilation 'De Legibus et Consuetudinibus Alamannorum' attributed to Ranulph de Glanvil, justiciar of England, and then it acquired the evil reputation of being a code prepared by Edward I., for the purpose of subjecting Scotland to the law of England. 'Upon an accurate collation of the books,' says Mr. Innes, 'it appears that the first part of the fourteenth and fifteenth centuries the local customary law of Scotland when they had happened accidentally, the vitiated or unintelligible text of the Scotch book is readily corrected by a comparison with the English author. There are, however, chapters in the 'Regiam,' which are not in Glanvil. Part of these are from the civil and canon law, and the remainder, joined inartificially to the surrounding text, appear to be genuine chapters of antient Scotch laws, most of which can be traced to their sources in the statutes of the earliest times now collected.' Mr. Innes does not believe in the theory that the 'Regiam' was prepared under the authority of Edward I., but thinks its resemblance to the English compilation may be attributed to the spirit of imitation. The 'Regiam Majestatem,' so named from the words with which it commences, is, with the burgh laws, and other vestiges of early legislation, printed in the first volume of the edition of the Scottish statutes issued by the Record Commission. None of the contents of this first volume, however, come within the description of the accepte statute law of Scotland. They are curious vestiges of constitutional history; and are, for the most part, of no settled principle of law by a reference to its origin, these old collections are sometimes referred to; but they are not admitted as direct authority in the substance of the law. The earliest reference to the publication of the statute law, and they specifically published a series of statutes reaching from 1424 to 1564. It is at the former date that the statute law, properly speaking, commences, and it proceeds thence in a regular series to the Union with England. Several of the most important statutes still in force—as, for instance, that which secures to the agricultural interests of Scotland the security of the tenure of the death of the landlord by whom it may have been granted—date back to the earlier part of the fifteenth century. The Scottish acts are referred to by the date of the parliament in which they are passed, and their numerical order: as, the 'Statute of Scotland Act 1424,' c. 25; 'The Act 1661, c. 16.' The early statutes are brief and sententious, and were admired by Bacon for 'their excellent brevity.' The following are two such statutes:—

Item, it is decreed be the hall parliament, and forbidden be our sovereign lord the king, that any leagues or bandes be maid amongst his lieges in the realm; and gif one has been made in time bygone, that they be not kept nor halden in time to com.'

'Item, it is ordained that no horse be sold out of the realm, quhilt at the least they be three yeir aird outgone, under the pene of escheat of them to the king.'

From the date of the accession of Bruce, after the war with England, the Scots long entertained a feeling of national jealousy and enmity towards England; and though some of the kings of Scotland were in constant communication with their English counterparts which had resulted into existence with the growing influence of the burghs. The coincidence between these early vestiges of Scottish legislation and the old law of England is remarkable. Burghs in Scotland and in the burghs of the technical phraseology is frequently used, which still belongs to the law and practice of England, but has long been discarded in Scotland. Indeed, it is very clear that, before the attempt of Edward I. to rule the realm, there was a harmony in the law and spirit between the two nations, and that Scotland generally followed or accompanied England in all her constitutional progress. There is still a more remarkable coincidence of English law with English legislation. English Justices, or officers of the general code of the old laws of Scotland. It was, like the fragments mentioned above, attributed to David I., who had obtained the character of the Justiciar of Scotland; but it is undoubtedly a part of the English law in the sixteenth and seventeenth centuries it was very popular, as an understood national code; but it was subsequently discovered to have many features in common with the compilation 'De Legibus et Consuetudinibus Alamannorum' attributed to Ranulph de Glanvil, justiciar of England, and then it acquired the evil reputation of being a code prepared by Edward I., for the purpose of subjecting Scotland to the law of England. 'Upon an accurate collation of the books,' says Mr. Innes, 'it appears that the first part of the fourteenth and fifteenth centuries the local customary law of Scotland when they had happened accidentally, the vitiated or unintelligible text of the Scotch book is readily corrected by a comparison with the English author. There are, however, chapters in the 'Regiam,' which are not in Glanvil. Part of these are from the civil and canon law, and the remainder, joined inartificially to the surrounding text, appear to be genuine chapters of antient Scotch laws, most of which can be traced to their sources in the statutes of the earliest times now collected.' Mr. Innes does not believe in the theory that the 'Regiam' was prepared under the authority of Edward I., but thinks its resemblance to the English compilation may be attributed to the spirit of imitation. The 'Regiam Majestatem,' so named from the words with which it commences, is, with the burgh laws, and other vestiges of early legislation, printed in the first volume of the edition of the Scottish statutes issued by the Record Commission. None of the contents of this first volume, however, come within the description of the accepte statute law of Scotland. They are curious vestiges of constitutional history; and are, for the most part, of no settled principle of law by a reference to its origin, these old collections are sometimes referred to; but they are not admitted as direct authority in the substance of the law. The earliest reference to the publication of the statute law, and they specifically published a series of statutes reaching from 1424 to 1564. It is at the
them to be enforced is to be found only in England. In many
instances these acts have only been capable of enforcement in
Scotland by reading, instead of English institutions, those of
Scotland, which most nearly correspond with them—as, by sub-
scription to the Act of Parliament—"The Athenaeum Record at
Westminster." The remedy for this evil appears to be, to incorpo-
rate with each act a clause stating the terri-
torial extent of its application; and whenever it is intended
that it shall apply to Scotland, to have clauses especially appli-
cable to its enforcement in that part of the empire.

STATUTE OF FRAUDS. This name is applicable to any
state the object of which is to prevent fraud, but it is par-
special to the 29 Car. II. c. 3, which is entitled
'The Statute of Frauds and Perjuries.' One object of the
statute was to prevent disputes and frauds by requiring in
many cases written evidence of an agreement. Before the passing
of this statute many conveyances of land were made without
any writing as evidence of the conveyance. An estate in
fee-simple could be conveyed by livery of seisin, accompanied with
proper words, and a use could also be declared by parol.

No writing was necessary to convey any estate in possession,
for such estate is technically said to lie in livery; but a reversion
could only be conveyed by deed. The statute of frauds de-
clares that every contract for sale of an estate for a greater
period of years, or any uncertain interest in any lands or heredi-
ments, made by livery and seisin only, or by parol, and not
in writing and signed by the parties, &c., shall have the force
and effect of a principal point to be proved in any suit for
more than three years, whereas the rent reserved shall be two-thirds
of the full improved value of the thing demised, are excepted
by the statute. Further, no lease, estates, or interest either of
the soil or reversion, or any estate or heredita-
ments, shall be manifested and proved by some writing
signed by the party who is by law enabled to declare such
trust, or by his last will in writing, or they shall be void.
The fifth section, or the other, or the different in the
relation to the revocation of a devise in writing of lands or
tenements, as more particularly described in this section,
should be in writing and signed in the manner here prescribed
by three or four credible witnesses; and the 6th section
related to the revocation of a devise in writing of lands or
tenements, which may be omitted here, as the object is to show merely
that the purpose of the statute is to prevent fraud by requiring the
evidence of writing, which is a better kind of evidence than
parol.

STATUTE MERCHANT. [Acton Burrell, Statute
of, P. C. S.]

STATUTE STAPLE. [Staple, P. C. S.]

STATUTE SHIP. [Screw or ARMERIES, P. C. S., p. 111, and STEAM VESSELS, P. C. S., p. 610, in the practical application of such
apparatus to steam-vessels, and results have been
obtained which lead to the conclusion that this mode of propulsion is
practicable upon a very large scale as well as in small
vessels, and that it possesses some very important advantages
over the use of paddle-wheels, the invention yet remains
too experimental a state to justify any attempt to deal with it as
settled branch of science. Since the date of
the articles referred to, in addition to vessels of more ordinary
dimensions, the screw-propeller has been brought into use in the
immense iron steam-ship now called the Great Britain, but
which, while building, at Bristol, was sometimes referred to as
the Mammoth, the dimensions of which, as given in the 'Athen-
aeum' for 1844, p. 114, are 590 feet long and 560 feet broad in
the widest part, drawing 16 feet 8 inches. In capacity is
about 5000 tons, and the engines, consisting of four cylinders of
88 inches diameter and 72 inches stroke, are of 1000-
horse power; and, although the screw-propeller was not at the
greatest ever launched, was fitted, on her completion in 1845,
the screw-propeller 154 feet in diameter, with six arms, mounted in
the stern, and capable of being turned with great rapidity
by a person standing on a circular platform, which was
immediately connected with the engine by a cord, which
motion through an endless chain to a much smaller wheel
fixed on the shaft, which constituted the axis of the prop-
eller. The propeller was thus turned with a velocity ex-
ceeding that of the crank-axis in a ratio determined by the
relative diameters of the larger and smaller chain-wheels.

Thus mounted, and driven by the engine, the ship was stepped on deck so as to be removable at pleasure, with
wire rigging, and with every requisite for taking advantage of
favourable winds, the Great Britain sailed from Liverpool on
the afternoon of July 26th, 1846, on her first trans-Atlantic
voyage, and reached New York on the afternoon of August 10th.
After her fourth voyage (the second homeward trip),
wherein she was left for some time wholly dependant
on her sails, in consequence of the shattering of the propel-
lor, she was fitted with a new and much stronger prop-
lor, weighing seven tons, of the same diameter as before,
but consisting of only four arms or vanes; and she was at the
same time fresh repaired, her number of weeks reduced to
five, and the whole stepped upon the keelson. With these
alterations, in an experimental trip made on the 50th of May,
1846, the Great Britain attained a speed of 14 knots,
and a speed still greater was attained on a voyage

An important discussion upon screw-propellers, suggested
by an account of a new steam-vessel called the Liverpool
Screw, submitted to that body, was carried on during three
sessions of the Institute of Mechanical Engineers, from
February 25th to 29th, 1844. In the course of this discussion,
which a full report was published in the 'Mechanics' Magazine,'
vol. xl. pp. 201-209, it was remarked by Mr. Bennie that the
steam-propeller was at a second stage of development,
which shall offer but little obstruction to the water, and yet
act upon it so as to exert full power in propulsion;

very large portion of a complete screw having no useful effect,
the water has been observed to flow without the aid of the screw blades; thus doing away with the useless part of the surface.'
A perusal of the discussion alluded to will show that the
engineers who took it for granted, in the chapter of the 'princ-
ple by which appears to be
meant the amount of motion absorbed by the propeller cutting
its way through the water, instead of pushing the water from
between the screw blades, a mass might be deduced from the number of revolutions made by
the screw, and the actual way made through the water.

Without attempting to unravel this somewhat difficult ques-
tion, upon the true comprehension of which the best shape,
size, position, and velocity of the propellers must depend, we
may observe with Mr. Farcy that while the advantageous
action of ordinary paddle-wheels is greatly impai by varia-
tions in the degree of immersion, the submerged screw prop-
eller, being wholly under water at all times, does not appear
to be sensibly affected by any such alterations in the depth of immersion as are likely to take place in the roughest waves,
neither the greatest variations of draught from the
the lading of the vessel. 'When all circumstances were con-
idered,' Mr. Farcy, observed, 'it might be safely concluded
that vessels fitted with revolving submerged propellers
would enable the greatest possible number of vessels, and
summer; and, on an average, he thought that their passage
would be performed at least as well (if not better) than those of
any steam-vessels now in use; and with an economy of
fuel, arising from such vessels making a more advantageous
use of their sails, and less of their engine-power.'
The absence of the ponderous paddle-wheels and paddle-boxes of
an ordinary steamer greatly improves the sailing qualities of
a screw-propelled vessel, while the arrangement of the ma-
achinery may be such as to render the vessel far more com-
venient, and, if desired, to leave the upper decks open from
end to end. These, among other advantages, recommend
this mode of propulsion for frigates, and other vessels of
war. The Princetowan, an American steamer-frigate, launched
about the commencement of 1844, and mounted with
Eriksen's transversal screw-propeller, affords a good example of
the advantages of the invention in application to ship-
building.

This vessel, which, according to an account quoted in the
'Athenaeum' for 1844, p. 206, from the 'New York Herald,'
is of 700 tons burthen and 250-horse power, has a submerged
propeller making 70 revolutions per minute, and is capable of making its way through a current of
14 miles per hour, or even somewhat more, as is said to have
bathed the Great Western in speed, although drawing at the

Since the above was written, the M. athens vessel was again appeared in the Bay of Dardanelles, between Batavia and Dacca, the screw-propeller engines,
which were used outward voyage, in the night of September 26, 1846; and though the spring-
tides have since taken place, her performance (Oct. 25, 1846) been g
time four feet more water, and exercising only two-thirds of her steam-power. The dimensions of the vessel are not given in the article quoted, but Mr. Braithwaite stated them, as above referred to, to be 164 feet long on the water-line, 22 feet beam, depth of hold 22 feet 6 inches, and draught of water 17 feet 6 inches. He also, if the report we have quoted be correct, stated the power of the engines as 400 horse-power, and the velocity of steaming of the vessel as rather less than we have stated. In the absence of proof as to which statement is correct, we may observe that while Mr. Braithwaite’s would indicate a very unusually high proportion of power to tonnage, that of the New York Herald shows the usual proportion for fast vessels. The engines, according to Mr. Braithwaite, are of peculiar construction, having two steam-cylinders or chemical engines, each consisting of six large, peculiar, circular plates, with cranks attached to the ends of the suspending pivots; these are coupled by connecting-rods to a main crank on the driving shaft, and the length of the first-mentioned cranks is so proportioned that their alternate vibrations shall give a rotary motion to the main crank, and thus act directly upon the propeller, without the intervention of bands or gearing. In a subsequent stage of the discussion this point was reverted to by Mr. Galloway, the advantage of turning the propeller by the direct action of the engines being, he said, generally acknowledged; indeed, he added, ‘the method of driving it was nearly only the problem remaining for solution, and that difficult problem was overcome, and steam-propellers must necessarily, from their vast advantage over paddle-wheels, in every respect but that, be universally adopted.’ Returning to the Princeton frigate, we may observe that it is evident, as stated in the New York Herald, how great advantage would mounted have the advantage over those of the usual construction in active service; for in that vessel the whole of the machinery, cranks, boilers, and furnaces, as well as the propeller itself, are below the water line, the top of the highest plates of the boilers being as much as four feet below, and therefore pretty secure against injury from shot, while in the Great Western, and other steam-ships of the ordinary kind, the machinery, as well as the paddle-wheels themselves, are within destructive range. We may mention, although not directly affecting the use of the screw-propeller, that the Princeton is supplied with furnaces for burning anthracite, to prevent the production of smoke, and that she is ship-rigged, and so constructed that in favourable weather her screw may be unshipped, when she will sail well under canvas, a facility which can never be so perfectly attained with the use of paddle-wheels.

The Liverpool Screw, an account of which formed the basis of the discussion to which we have referred, is a small iron vessel, 60 feet long, 12 feet 6 inches beam, and drawing 5 feet 6 inches. She was mounted with a wheel of 3 feet 10 inches diameter, but it had been enlarged at three several times, and was, at the date of Mr. Grantham’s account to the Institute, 5 feet 4 inches diameter by 20 inches long, of which 13 only were immersed; a part of the propeller being constantly above the water. It was turned with a velocity of 95 revolutions per minute, by means of two high-pressure oscillating engines, working one crank upon the main driving shaft, without the intervention of gearing or bands; and the nominal power of the engines was 20 horses, though the effective power rarely exceeded 16 horses. Though the proportions of this little vessel were not deemed favourable to a high speed, her length being only five times her beam, and her sectional displacement 25 feet, she was found, in a number of experiments, capable of beating all the steamers upon the Mersey, excepting the large sea-going vessels, and was proved to have a great superiority over other steamers in towing vessels out in a heavy sea.

Many observers have stated that the usual position of the screw-propeller, immediately before the stern-post, does not appear either to be disadvantageous for the application of the propelling power, or to interfere with the action of the rudder; and it is intended by the introduction of it to increase the efficiency of the rudder. Under the impression however that a contrary result takes place, it was proposed, in Maudsley’s patent of 1843, to put the propeller behind the stern-post, in the position usually occupied by the rudder, and to employ two rudders, placed beneath the stern quartermaster, a little in advance of the propeller.

An important use to which screw-propellers have already been applied in a few instances, and for which it is highly probable that they may be extensively adopted, is as a mere auxiliary power, for occasional use during calm and contrary winds. The English ships Audacia and Euphrosyne, which are regular sailing vessels, fitted with conveniences of a very superior order, is provided with a small Ericsson propeller, 9 feet in diameter, and has a steam-engine which can be set to work when required, of 170-horse power, capable of producing a speed of about 9 miles per hour in smooth water. The propeller is so constructed as to be raised out of the water when not in use. In sailing from Liverpool to America the Audacia made the voyage, from February 22 and November 18, 1846, gained from five to thirteen days as compared with five other ships which sailed either on the same or on the following day. The cost of the motive power in this vessel was about two-sevenths of her total cost, which was about 16,000L. In a similar way an auxiliary screw-propeller is ordered to be fitted to the Amphion frigate, which was launched at Woolwich in January, 1846, and which, though she is to be furnished with a screw of 15 feet diameter, and engines of 300-horse power, which will render her quite efficient as a steam-vessel, has been built as a sailing ship, her construction having been commenced as long since as 1830. We believe that the British navy with her machinery entirely below the water-line, as in the American frigate Princeton.

These destructive investigations of the history of screw-propellers, and the attempt at their application to the construction of new vessels, are the subject of the discussion which we have quoted, an ample chronological list of patents and inventions relating to the subject, from 1727, about which time a plan for propelling vessels up a river by means of a screw was contrived by Professor Franklin; by M. Duquet, to the year 1843, in the ‘Mechanics’ Magazine,’ vol. xxxix. p. 292, with addenda on pp. 340 and 360 of the same volume.

STEENHAMMAKER, a genus of plants belonging to the natural order Boragineae. The calyx is divided into five deep segments. The corolla bell-shaped, with a short cylindrical tube with 5 minute protuberances in its throat. The stamens protrude beyond the throat, the stamens elongated.

S. martima, the only British species, differs but little from Lithophragma except in habit. It has a procumbent branched stem, ovate, acute leaves, with rough, hard dots, glabrous, fleshy, and glaucous, having a taste resembling oysters. The nuts are smooth. The flowers in racemes and of a purplish blue colour.

(Babington, ‘Manual of British Botany.’)

STEVEN, or Jacob QUÉS, born at Lyon, in 1565, his father, François Stella, who was also a painter, died when he was only nine years old. Notwithstanding the early age at which he lost his father, Stella is said to have had no other master. He was the son of a rich merchant of Lyons, and when he was employed by the Grand-Duke Cosmo II. to execute the decorations which were designed for the celebration of the marriage of his son Ferdinand II. Stella made many designs and painted several pictures for the grand-duke, who gave him apartments and allowed him a similar pension to that which he gave to Callot the engraver. After living seven years in Florence, Stella went to Rome, in 1625, and contracted a friendship with Ponzio, of whom he became also an imitator.

While in Rome he was, by some treachery or misunderstanding, thrown into prison, and while in confinement he masqueraded himself in a drawing on the wall, in chalk, the figure of the Virgin with the infant Jesus in her arms. A report of the excellence of the drawing reached the Cardinal Barberini, who went to see it, and from that time a bright lamp was suspended over it and the prisoners performed their devotions before it.

In 1634 Stella returned by Venice and Milan to France, with the intention of visiting Spain. At Milan they offered him the title of baron; he declined the proffered honor, and went on to Spain, whither he had been invited by the king. Cardinal Richelieu however succeeded in detaining him in Paris; he procured him apartments in the palace of the de Montmorency, and an annual pension of 1000 francs. In 1644 he was decorated with the cross of St. Michel and was elevated to the rank of principal painter to the king. He died at Paris in 1657.
Stella remained an imitator of the style of Poussin, but he did not go beyond the drawing and colouring of Poussin, and on the latter he exaggerated the defect of Poussin: many of his pictures are very red. He excelled in pastoral pieces and at the age of twenty-seven he had engraved some of his greater works. He etched five plates himself, which are very scarce, namely, The Descent from the Cross; A Madonna; A Saint George; a genre piece with infants dancing; and a large etching of the Presentation of Tribute to the Grand-Duke of Tuscany, of the date 1621, which is very rare. Many woodcuts, apparently by P. Maquin, are marked 'Stella feitt,' but this alludes to the design, not the woodcut.

(Felician, Entr’o, ord.; D’Argenville, Vies des Peintres, etc.; R. Dumenil, Peintre-Graveur Francais.)

STENEOBIAUS, a crocidilion genus of fossil Silurian marine snails. The type is E. cereale, the index fossil which forms the Triassic-Permian boundary. (Goodrich.)

STENELYTRA (Insects), the third family of heteromorph Coleoptera in the arrangement of Latreille. Holops, Cistel, Derex, and Stenemera are examples. They are known by the convexity of their antennae which are thickened at their extremities. They live under the bark of old trees, or on leaves and flowers.

STERNBERGIA (Bronnmiart), the generic name for a stemless plant from South America, apparently. In the subfamily of the Polygalaceae by Bronnmiart. Mr. Daws has compared it to the interior of some tree stems in which the pith is transversely divided by phloem. It has been also named Artisia by Pfeil.

STERNOPTYX, a genus of small flies belonging to the order Salaminidea, though very different in aspect from salamandrous or trout-flies. They have very elevated and much compressed bodies. They live in the warmer regions of the Atlantic Ocean.

STEWING is a process in cookery by which meat or vegetables are made fit for food by immersing in water at a high temperature for a considerable period of time. It differs from boiling by the temperature of the water not being allowed to reach 212° Fahr., and by being continued for a longer time. The effect is that of very thoroughly softening the substance used and the retention to a great degree of the flavour of the meat or of the spices added. These ends are accomplished by employing vessels with very closely fitting lids. The material of which these vessels are made is commonly earthenware, of Adams clay, and as a confession of the German enamelled stewpans, so safe, and so well suited, from the extreme nicety of the composition, resembling earthenware or china, with which they are lined, to all delicate and easily destructible confections. They must be kept very clean, and the timing always perfect. If this be rubbed off acid and saccharine liquids form poisonous compounds, which produce serious and occasionally fatal effects.

When several stews or made-dishes are prepared at the same time, a bain-marie, or water-bath, is the best apparatus. This is a flat vessel containing boiling water: all the stewpans are put into the water, which is kept always very hot, but must not boil; the effect of this is to keep everything warm without altering either the quantity or the quality, particularly the quality.

'Gentle stewing is incomparably the best—the meat is more tender, and the soup better flavoured. By quick and strong boiling the volatile and finest parts of the ingredients are evaporated, and fly off with the steam, and the coarser parts are rendered soluble; so you lose the good and get the bad. The full flavour of the ingredients can only be extracted by long and slow simmering; during which, take care to prevent evaporation by covering the pot as closely as possible.'

(Dr. Kitchener’s Cook’s Oracle.)

STIEGLITZ, CHRISTIAN LUDWIG, was born December 12th, 1766, at Leipsig, in which city both his grandfather and father were persons of station, the former, who died in 1736, a burgomaster, and his father, a wealthy merchant, and an officer of protocol. Surrounded at home with objects of art, for his father possessed both a collection of pictures and a cabinet of medals and minerals, Stieglitz imbibed from them almost in his childhood those tastes which so assiduously cultivated throughout life, although they were altogether remote from his other studies and occupations. Though he set his father’ s study in 1771, and in 1773 he published in Leipzig a treatise on law, he wished he applied himself to jurisprudence and other studies at the university of his native city, where he attended the courses of all the most eminent professors of that day, Ernst, Clincker, Platzer, &c., and took his law degree in 1777, and in 1784 that of doctor of laws, on which latter occasion he produced his dissertation 'De Caesis cur Jus Feudales Germanicum in Germania ngestem cit.' In the latter year he devoted all his time to literature and art, and in 1775 made his first essay in poetry, in which, if he did not distinguish himself, he continued occasionally to exercise his pen, for he contributed many pieces to a collection of Kriegslieder, or War Songs, published in 1776, and in the published 'Wartburg,' a poem in eight cantos, which appears to have attracted so little notice, that though biography has preserved its title, the production itself has obtained no permanent record in literary history. He also published some tales of romance and chivalry; but it was in a very different field from that of the poet or novelist that he gained his reputation and rendered essential service to a branch of literature which had hitherto been neglected. In 1781 he published an essay on the fashions and fancies of the times in Wissenschaften' several essays and minor treatises on various subjects relative to the aesthetics of architecture and decoration, one or two of which appear to have been also published under a similar guise, as papers in the Allgemeine Correspondenz of the chief member of the Bathicollegium, or Council of Leipzig, he first brought out his 'History of the Architects of the Antients' (‘Geschichte der Baukunst der Alten’); and immediately afterwards engaged in a work of the same kind, the 'Encyclopedia of Civil Architecture,' in five volumes, the first of which appeared in 1792, the last in 1798. In the interval he brought out a work upon Modern Gardening, which came to an end without competition. The latest production was his 'Artistische Blätter' (1800), a collection of papers on Decoration. In 1804 he began to publish, under the title of 'Zeichnungen aus der schönsten Baukunst,' a series of engravings, plans, and elevations, intended as select specimens of modern architecture; but though it was exceedingly well received—for not only did it come to a second edition but there was also a French one—the choice compromised both his judgment and taste, the majority of the specimens partaking of that feeble and inartistic manner which had just before prevailed in this country; and a great many of the subjects were taken from English publications—those, for instance, of Adam and Ellis, of Batty and Adam, and among others such examples as the Trinity House, London, and the County Hall at Chelmsford. How he could reconcile them with his own theoretical principles is difficult to be understood.

Whether it was owing to his being satisfied with what he had then done for architecture, or afterwards dissatisfied with his last work, some years elapsed before he again published anything on the subject, turning in the interim to studies more professsionally archaeological; the fruits of which were an essay on Medals and Collections of Coins,' 1809, a treatise on the 'Pigments employed by the Artists of Antiquity,' 1818, and 'Archaeological Undercurrents,' 1820. In the same year with the last-mentioned publication came out his excellent work on Ancient or Medieval German Architecture (Alt-Deutsche Baukunst), which contributed not a little to direct attention to and inspire that study for medieval art and its monuments which has since struck root and grown up in Germany. His next work was his 'Geschichte der Baukunst,' a valuable compendium of the history of architecture from the very earliest periods, that appeared in the first editions of which appeared in 1827, and the second, a greatly enlarged one, in 1837. Contrary to the opinion of Hirt (Hirt, P. C. S.), Stieglitz contends very strongly that the characteristic features of the Gothic were developed in the characteristics from an original construction of stone, and not of timber or wooden framing. The list of his literary labours is further extended by his 'Distribuzione Numismatica Germaniae,' 1833, and 'Geschichte der Ausbildung der Baukunst,' 2 vols., 1834; and it would be prodigiously increased were it possible to enumerate...
all the various articles which he contributed to the 'Ieremon,' the 'Kunstblatt,' and other journals; and to Ezech and Grätz's 'Encyclopedia.' After having held the office of professor of the military history of Leipsic, he was appointed one of the assessors connected with the town government, Stiglitz retired from public duties in 1830, though he retained the title and distinction of proconsul; and in 1834 the 'juveniles' or fifteen annual volumes of his works was celebrated at his townsmen, and a silver medal was struck and presented to him on that occasion. He died July 17th, 1836.

In Forster's 'Bautzzeit' for 1838 there is a portrait of Stiglitz accompanying a full memoir of him, which we have made use of for this article.

STIGLZI{ER, JOHANN BAPTIST, the late distinguished director of the Royal Bronze-foundry of Munich, was born on the 29th of June, 1776, at Fürstenfeldbruck, a small market-town near Munich, where his father carried on the business of a blacksmith. At Fürstenfeldbruck is an old foundry converted by Ludwig the Strong, of Bavaria, in atonement for the hostile execution of his innocent wife Mary of Breslau, in 1780. This converted, which had undergone various changes, and had been at various times extensively decorated, was the school and academy of the barefooted blacksmith's son, though in his time it was a military stable for foals (Militär-ofohlenhau). It contained stucco decorations by E. Asam,frescoes by Appiani, statues by Roman Boos, and other works of the last century. This building, as already observed, was Stiglizer's academy, and in the library of which there was a reprint of the woodcuts of a book on natural history, which, with a catechism and prayer-book, constituted the whole library of his family. These woodcuts and the decorations of the convocation were diligently copied by Stiglizer, who was so busy painting away that he was obliged almost to go daily for milk), at length ventured to introduce himself to the superintendent of the establishment, Herr Pfieffer, who he heard was not only himself a drabman, but possessed of some real painting energy, and gave him some regular elementary instruction in design. After this he was placed by his parents with a goldsmith at Munich, of the name of Streel, and he attended in the meantime the holiday school (Ferienkurse), in which he obtained the first prize for industry and good conduct, amounting to 100 florins (8 guineas), by which he attracted the notice of M. Leprieur, the director of the Bavarian mint, who from this time took much notice of Stiglizer, procured him admission into the academy in 1810, and became in a manner his patron. From the date of his admission into the academy, he pursued the regular course of study requisite for a statuary and sculptor, and at the same time practised seal and medal engraving. He was very successful in 1814 in a medal for Von Langer, the director of the Academy, on one side, and Moses making the water flow from the rock on the other, which he was appointed to the engraving of the mint, and he was sent in 1819, at the king's expense, to Italy to complete his studies.

It was in Rome that Stiglizer's great patron, Ludwig, the King of Bavaria, (then Prince) first became cognizant of his high abilities, and appears himself to have directed Stiglizer's attention principally to metal-sculpting, in preparation for his own great undertakings already projected by him. In reference to this future occupation Stiglizer repaired to Naples to witness the casting of the bronze colossal equestrian statue of Charles III., to be directed by Francesco Righetti and his son Luigi, from the model by Canova; the Italian sculptor's reserve and jealousy, however rendered Stiglizer's journey in vain as regarded its principal object; he did not allow him to see the casting. But in another respect he was fully compensated; after considerable trouble he obtained permission to erect a pedestal, sconce and cenotaph in his cellar, and having procured the assistance of Beechest, an experienced foundryman, then to be found even in the principal cities of Europe, he undertook the casting of several works himself. The first wholly failed, but the second, a cast from Thorwaldsen's bust of Ludwig I., then crown prince, was completely successful, so much so, that the journeyman, Pasquili, in his ecstasy kissed the tip of his pencil, which he had so long been searching for in vain, because he had not the courage to write his own name on it in true Roman style. He returned to Munich in 1822, but was at this time employed chiefly in his capacity as engraver for the mint, and on some unimportant works of sculpture for the new Sculpture Gallery or Glyptothek then in progress. To the medals of this time belong that in commemoration of the marriage of the King of Prussia, for the minister Von Zentner, and the various medals for the Equestrian statues of Louis Napoleon, which were those of King Maximilian I. and the Queen Theresa, Count Döring, the ministers Baron Von Zentner, and Lerchenfeld, Bishop Streber, and others.

In 1824 Stiglizer published a work 'On the great variety of metal castings, and from this time he was exclusively employed in founding the numerous monumental works which have been executed for Ludwig I., the present King of Bavaria, some of which are the most extensive castings of modern times. In order to be as well prepared as possible for this arduous task previous to casting any great monument, he visited Berlin in 1824, to witness the casting of Rauch's colossal statue of the Elector Maximilian I., which showed him everything in his power. Stiglizer's great activity commenced with the reign of Ludwig I., in 1826, in the foundry established and afterwards much enlarged by the king, expressly for his own numerous undertakings in that important branch of art; and he left many, and the most considerable still unfinished, at his death. He was created in 1839 Knight of the Bavarian order of St. Michael.

The following is a brief summary of his labours—from his own designs—the monument to the Brazilian children Juri and Isabella, and the reclining figure of the Franklin Von Mannlich, in the cemetery at Munich; the monument of Maximilian I., in the cemetery at Munich, the monument of the parting of Otto, king of Greece, from his mother Therese, queen of Bavaria, at Ailing; after Schwanthaler—the twelve colossal fire-gilded statues of the ancestors of the King of Bavaria, ten brass statues of the ministers of the King of Bavaria, the statue of General Bekker for his monument in Munich; the colossal monumental figures of Jean Paul in Bayreuth, Mozart in Salzburg, the Margrave Frederic of Brandenbourg in Erlangen, and the Grand Duke Ludwig in Karlsruhe, and the gilt bronze pieces of table-service, with designs from the Nibelungen and Aenomenia, for the crown-prince of Bavaria; after Thorwaldsen—the statue of Schiller at Stuttgart, and the monumental statue of Baron Stiglizer, and the monument of the gilded candelabra in the new throne-room in Munich; the monument to the brave Oberst Streissl, at Aibling, and the monument to the hero of the battle of Leipzig, and the tomb of King Maximilian I. in the royal vaults (Fürstengruft) at Munich, after a design by the architect Ziehend. Besides the above works, which are completed, are the following练习 the casting of the busts of King Ludwig III., and Stiglizer's death—the colossal statue of Goethe, for Frankfurt, after the model by Schwanthaler; and from the model of the same sculptor, the enormous colossal figure of Bavaria, nearly sixty feet high, to be placed before the Baldur's temple of Fame, or Ruhmehalle (now in progress in the suburbs of Munich, and which will be completed in 1850). It is the largest statue in the world, measuring, with its pedestal, eighty feet; also, by Schwanthaler, the monument of the late Grand-Duke of Baden, with a pedestal and four allegoric figures of the four circles of the dukedom; and the statues of Marshal Tilly and Wrede, for the now marquis' Leggira or Feldmühle at Munich; and cast from Thorow's models of the statues of Ferdinand, king of Naples, and of Bolivar, for Boliva, in South America.

Stiglizer died March 2, 1844, on the day on which the statue of Goethe was cast by his nephew and assistant Ferdinand Miller. Stiglizer had suffered from illness two years previous to his death, and many supposed it was owing to the unhealthy system of gliding by fire; but he died of a cancer of the tongue, which, while he was a physician, had previously declared to be the cause of his illness.

(Kunstblatt 1844: Seel, Bildende Kunst in München.)

STIGMANN, A genus of fossil plants allied to Lyopo-spermum, and which probably inhabited the beds of coal, whether Silurian stand over these beds or not. It is most abundant in the lower parts of the true coal formation.
STILL, JOHN, the son of William Still, of Grantham, in Lincolnshire, was born in 1643, and became a student of Christ's College, Cambridge, where he took his degree as Master of Arts. In 1670 he was appointed Lady Margaret's Professor in the History of Living Things at the University of Suffolk and Yorkshire, and was subsequently Master of St. John's and Trinity Colleges. In 1658 he was chosen proctor of the convocation; and, in 1693, he was raised to the bishopric of Bath and Wells, which he held till his death in 1707. Bishop Still is said by Fuller to have been 'one of a venerable presence, no less famous for a preacher than a disputant.' He left a large fortune, chiefly derived from lead mines discovered in the Metalliferous district during his possession of the see. The historians of the drama concern in believing him to have been, in his youth, the author of a coarse but humorous play, which, till the recent discovery of 'Ralph Royster Doyster,' was held to be the earliest extant work known in English by the name of a comedy. It is called, 'A Rhytg plity, pleasant, and merio Comedy, intytuled, Gammer Gurton's Needle, played on stage not long ago, in Christia's Collage in Cambridge. Made by Mr. S. Master of Art, 1675. 'Gammer Gurton's Needle' is in Hawkins's 'Origo of the English Drama,' and in the second volume of Dodsley's 'Old Plays.'

The soil of the county and the towns are very much affected by the tribe Stipocem.

It has staked stumps, the palisades, the inner entire.

S. parvula, the only British species, has a very long twisted feathery twin, with a glossy base. It is a very beautiful plant, and is found in our gardens. Found on rocks in Long stead near Kendal.

(STINNETT. Manual of British Botany.)

STOCKADE, in Fortification, is the name given to a wall constructed on the principle of the great Henry Maudsley's towers, or rough piles of timber, so as to inclose an area which is to be defended. The trunks or piles are planted close together; and at intervals of three feet from one another loops are tied through them, on which the trees, 8 inches long are cut down, vertically, from the top, through which the defenders may receive a fire of musketry on the assailants. An inclosure of timber so planted is sometimes called a Pillars, from the French word pillar (pioter). The first fortifications of the French, when they first entered Europe, to their field-redoubts or small entrenched camps.

Stockades are still frequently constructed as temporary fortifications in countries which abound with timber, as in North America and the East Indies; and, among uncivilized nations, trees, and rude paraphernalia, are the only kinds of fortification which have been executed. They were also, in general, the means employed by ancient armies while besieging towns, to protect themselves or to prevent the escape of the garrison. The walls with which the Peloponnesians surrounded Plataea during the siege, and the blockade of that city by the Romans, are stated to have been made, in this manner, in a double line with a certain interval between the lines (Thucydides, ii. 75); and the fortresses of the Drile, a people inhabiting the shores of the Euxine Sea, are described by Strabo as consisting of a similar kind of blocking, called embankments, on the latter of which were palisades and wooden towers.

The description of the Pha, or Hipahs, of New Zealand, which is given in the accounts of Captain Cook's voyages, would nearly serve for the stockades within which the natives of that country very recently resisted the assault of a British force. It is stated that the works consisted of trunks of trees planted close together, with a small inclination towards the interior space; and that at intervals from one another, particularly at the angles of the works, there were scafolds whose heights from the ground were three feet less than that of the top of the wall, so that the defenders were able to see the ground at the foot of the wall while they were concealed from the view of the enemy. In the interior there was usually a hollow place in which the women and children, with the provisions, were deposited. The pales are generally on the summits of heights, and they are sometimes strengthened by outworks of a similar nature.

On the frontier of the United States of North America, during the war, the planting of roughly-hewn trunks of trees planted close together in upright positions and pierced with loop-holes for musketry, are very frequently constructed for the purpose of inclosing an area which is to be defended; and in that way the foundations of a fortified house, serving as a bastion to flank the stockade, is constructed with very thick logs of timber placed horizontally:

These block-houses are sometimes formed with an upper story, the angles of which project over the sides of the lower one, so that by loop-holes in the projecting part of the floor a fire of musketry may be made upon the enemy when at the foot of the wall.

STOCKINGS. [WEAVING, P. C.]

STONE FOR BUILDING. The durability of stones may be examined in several ways, and results of much importance in the arts have been actually obtained by some lately. Investigations set *on* foot for the purpose of determining on a proper stone with which to construct the New Houses of Parliament. In their natural repositories the surfaces of rocks are exposed to weather and mechanical agencies connected with the atmosphere and dependent on the climate. Rocks which are composed in any considerable degree of carbonate, or carbonate, are cement, or which contain minerals into whose composition alinate of soda and various other acids, is stilled, is less favourable to their preservation. Not only the freely consolidated chalky rocks (like that of Mestersham), but the more solid Oolite of Bath and Portland, these rocks, or in the interior of the ancient towns, are often the same of the firmer most limestone of Derbyshire or half-crystallized and half-silicified marble of Yorkshire, being incapable of preserving its edges and angles from slow decay and disintegration, even in the most remote regions of the height of the mountain, or the comparatively low and tranquil regions of Devonshire. Even the purest crystallized marbles of Attica or Carrara, which may endure in the sunny regions of their birth, cannot withstood without injury to the moist and variable climate of Britain.

If, desiring to find a perfectly durable limestone, we turn our attention to other classes of rocks, we find other causes of decay equally influential on these. Limestones of this kind are the class of sandstones which comprises every degree of bad quality, but scarcely the highest degree of good,—the imperceptibly decaying millstone grit of the Drulwich Tills at Boroughbridge with the Craven limestones, to which the architectural beauties of Carlisle, Chester, and Coventry have been unfortunately wasted.

Granite scarcely merits universality, nor even generally, the reputation of a very durable stone in Britain. Some of the Cornwall and Devonian granite is of little permanence, much of that in Cumberland and the island of Arran is quite perishable, nor is all the stone of Killinc, near Dublin, free from the same reproach.

The decay of granite is usually ascribable to the unequal action of the atmosphere on its dissimilar and unequally resisting ingredients. The felspar often decays through the action of the chemical action of water, by which it is converted into the powder of heat and cold, of alternate wetness and dryness, and the change of the men of that which is compacted with the quartz and micas of granite. The arenaceous rocks however yield with too much facility to the hygroscopic and other changes of the atmosphere, and except we can obtain almost pure burnt sandstones with almost confluent grains we cannot be confident of their durability. Now, such sandstones, like the harder granites, are unfitted for architecture, however useful for walls, paving, and other rough purposes. Stonework must in general be freestone firm enough to sustain great pressure, and yet so aggregated as to admit of being worked with facility by ordinary tools, and of receiving correct surfaces in any direction. It must in general yield masses of great dimensions. Its colour is of consequence to the architect, who is necessarily attentive to this element of effect; and the colour which belongs to the stone is very often, indeed generally, much changed by the growth of lichen, the access of moisture, and the change of the contained iron. By so many conditions, indeed, is the choice of stone limited in a particular case, that very few samples of stone are really placed at the disposal of the architect.

In the great variety of limestones and sandstones which are adapted for building purposes, we remark, by the aid of the microscope, three principal modes of molecular aggregation: mixtures, which are aggregates of crystals; and compacted crystallizations.

To give an idea of the applicability of this classification, we...
may shortly review a small series of sandstones arranged in a geological sequence. None are mentioned except such as have been much used. Those which are not really freestone or which have not been found tolerably durable are inclosed in parenthesis.

Cambrian. Serpentine stone used in Serpentine, a mixed mass. It hardens on the surface by exposure.

The 'calcareous grit,' as it is called, of Yorkshire. It is a mixed mass (with little or no carbonate of lime). It is used at Doncaster Park; hardens by exposure.

The 'Kelley's' rock of Yorkshire: a soft mixed mass, very slightly calcareous, hardens by exposure. Durable in the vicinity of Hardness.

The ferruginous sandstone of the inferior oolite: a mixed mass; much used in the Midland Counties, and is often found in old churches well preserved, e.g. Northamptonshire.

The new red-sandstone of Penrith, mixed, durable: in the old Castle, Glan's grave. &c. (Other specimens of fine grain are among the worst stones of the district.) A light coloured sort, called 'Keuper', quarried near the Malvern Hills, is durable.

Palaeozoic. (Few of the sandstones of the coal-formation are of much durability, though many are of great beauty.) In the lowest part of the coal strata are good firm, rather coarse-grained, mixtures, as near Leeds; and below these the well-known millstone-grit, the base of the northern coal-fields. This stone was used by the Britons and Romans in the north of England. In the natural rocks of Brimham, the Devil's Arrows of Borrowbridge, and the abbeys of Kirkstall and Fountains, it has not well resisted the atmosphere; but its decay is slow.

The magnetic limestone, a crystallized mass, varies in its compactness. It varies also in texture, from a confused aggregation of crystallized grains, to a small cellular texture, the walls of the cells being composed of small crystals; and finally to a large cellular mass, the interiors of the cells being either compactly crystallized or filled with a soft earthy mass. In fine examples of this stone, as those of Mansfield, Bolsover, Anston, Boche, and Huddersfield, the cellular constitution is nearly the same (one atom of carbonate of lime to one atom of carbonate of magnesia), and it is in the mode of aggregation that we are to seek the explanation of the very superior durability of these to nearly all the other magnesian limestones.

The thick beds of the mountain-limestone are often used in building, but seldom very tractable in ornamental work, except the softer beds of the marble-season are adopted or imitated. It is in one considerable proportion of limestones, though, generally only a mixture of grains. These are in a considerable proportion of organic origin. The magnesian varieties of Derbyshire have more the character of ordinary freestones than the other varieties.

In considering even the few cases here adduced, we find mixed, concretionary, and crystalline textures, some of which are durable, others perishing. Mixtures of very various or very distantly related parts, as millstone-grit; concretions which have earthy textures in their interstices, as some oolite limestones; crystallizations which do not produce compactness, as in some magnesian limestones, and not in compactness, as the Serpent stone, the Colwick sandstone, and some mountain-limestones; concretions of adherent globules, as the oolites of Kettering; concretions of globules cemented by sparry interstices, as the oolite of Anston; and crystallizations with uniformly adherent grains, as in the magnesian limestone of Bolsover,—these appear to be durable. The microscope may determine in many cases between one class and the other. Additional evidence may be obtained by exposing masses of stone to frost and sunshine, rain and wind, to inhibition of salts which expand in crystallization, and to mechanical pressure. And there remains one further class of evidence more important in all respects. By observing how the various sandstones and limestones have behaved in castles and abbeys, and churches, we may attain with the highest probability a correct estimate of their intrinsic durability.

The commissioners (Mr. Barry, Sir H. D. de la Boche, and Dr. W. Smith) who reported on the choices of stone for the construction of the New Houses of Parliament, have neglected none of these considerations, and their report, certainly the most valuable document which has ever appeared on this subject, embodies a great mass of valuable statistical information on the most famous quarries; accurate notices of the most remarkable buildings which were constructed from these stones, and chemical analyses and mechanical experiments on the stone. The strength of several sorts of stone, as measured by the weight necessary to be applied for breaking and crushing them, appears below:
proved to be the Bath oolite from Box; that most in
herited by Brand's artificial process of disintegration was the
Barnack stone; and that which was most easily crushed was the
Bath oolite from Box. Generally speaking, Stones of the
waste which least absorb moisture least disinte-
grating; sandstones appeared to be strongest, though choice
magnesian limestones (as that of Bolsover, finally recommended
by the Commissioners) were fully equal in this respect, and
were almost as little absorbent. (Report of the Commissi-
oners, 1839.)

A few remarks on the appearance presented by stones in
decay may be of some service to the collector. Stones of
the same texture commonly decay by disintegration at the
surface, losing grain by grain in proportion to time and ex-
posure. But they sometimes suffer a singular change, as if
baked at the surface. An unusual enveloping crust is then
formed, as at Stonehenge, where the interior is soft, but the
outer hard. This process appears to render such a stone
durable. But if carried further, so as to produce a new
texture of the surface, the external shell separates from the
interior mass, desquamates and falls off, leaving a rough soft
inner core. This happens even to moulded surfaces like those
of balusters. Stones composed of parts unequally mixed suffer
unequal waste in different parts. Shells, corals, concretions,
and crystallized masses, also appear prominent from early
limestones, and indicate the general fact that, in proportion
the force of molecular aggregation in the stone, is the re-
sulting effect of the mode in which the original particles
are held together.

Again, the circumstances under which a stone is exposed to
a building influence its conservation. It is not the amount but
the kind of exposure which governs the decay. The southern
and western parts of Yorkshire and the north and
eastern parts of Hampshire. Prominent cornices are often perfect,
while below them the mouldings are reduced to shreds.
The drip-mouldings remain and is even hardened, while the parts
which it was destined to protect least moulded away. This
has actually occurred to the observation of the writer in the
space of only a few years. In fact since 1833 the same
pieces of magnesian limestone remain perfect in the drip-
moulding, showing every chisel notch, in the whole orna-
timents, while the rest have been totally decayed.

STONE, NICHOLAS, master mason to Charles I., was
born at Woodbury, near Exeter, in 1668. He lived three
years in London with one Isaac Jones, his master, and then
went to Holland, where he worked for Peter de Reyser,
whose daughter he married. He returned to England about
1614, and was for many years chiefly employed in making
monuments for the nobility and gentry. In 1610, he was
appointed master mason for building the new Banqueting
House of Whitehall, on which he was engaged two years at
4 shillings and 10 pence per day; and in 1626, at the com-
missionment of the King's Arms, he gave the designation of
master mason of Windsor Castle. The patent is in Rymers' Fodera, vol. viii., p. 678. The history of Stone's works is
fully recorded by himself in a pocket-book, which was in
the possession of Mr. Hawkinson, and is now in the hands of
Mr. Vertue. Stone obtained a copy. This pocket-book contained a full account of the various monuments he had executed, with the sums of money he received for them, and the names of the persons
for whom they were constructed.

According to this book, Stone erected in 1641 a monument
to the Earl of Ormond, at Kilkenny, for which he received
400L. He received in the following year 500L for a monument
to Henry Howard, earl of Northampton, erected in Dover
Cathedral. For a tomb made for Lucy Harrington, Countess of
Bedford, 1616, he bargained for 1000L, besides the charges
for carriage and iron and setting up. This year he went to
Scotland, where he had business in transactions there—July, 1616, was I sent to Scotland, where I undertook to do work in the King's Chapple and for the King's Closet, a great part, so much as came to 400L of which I have finished. I performed and had my money well paid, and 50L was given to drink, whereof I had 20L given to me by the king's command. He mentions drink-
money on other occasions. Stone made several monuments for
Queen Elizabeth and for Henry VIII., and received 101L, 17s. 8d. for the post, for which the Countess of Dorset paid him 404L.

In 1625, he made for the Old Exchange of London four
monuments—Edward V., Richard III., Henry VII., and Queen
Elizabeth; for which he received 123L, 10s. 4d. For the three kings he received 252L, each, for the queen, 30L. 25s. appears to have been Stone's ordinary charge for a
monument, including the pedestal.

Stone received altogether nearly 12,000L for the various
monuments erected by him. The various sums for monu-
ments noted in his pocket-book, amount altogether, ac-
cording to his own account, to 20,000L. From whom Vertue
acquired his information concerning Stone's family, to 10,880L.
Walpole has given a list of the principal monuments, and
mentions some architectural works by Stone. He died
July 24, 1641, and was buried, according to Michaelmas'
Church, where there is a slab to his memory with an inscrip-
tion and his profile. His wife and son Nicholas are buried in
the same grave: they both died in the same year a few months after him. Stone had three sons, Henry, Nicholas, and John.

Henry Stone, known as Old Stone, probably because he
was the eldest, was a statuary and painter, but he was chiefly
engaged in painting. He studied in Italy and the Netherlands,
and made many excellent copies of celebrated Italian and Flem-
ish pictures; there is a large copy at Hampton Court of the
celebrated picture, by Titian, of the Coronna Family, now in
the possession of the Duke of Northumberland. He lived in
Long Acre in the same house that was his father's, which he
rented for the crown for 10L per annum. He died in 1653,
and was buried near his father; and the following inscription
to his memory was placed in the church by his brother John:

"To the memory of Henry Stone of Long Acre, painter
and statuary, who, having passed the greatest part of thirty-seven
years in Holland, France, and Italy, achieved a fair renown
for his excellence in the profession of his art and languages.
In the prime of his life on the 24th day of August, a.d. 1653, and
lyched buried near the pulpit in this church." Here follows some laudatory
verses. Old Stone wrote a book, entitled 'The Third Part of
Stone's Account of the Art of Painting,' in which he described many cele-
brated works. Mr. Bird, the statuary, says Walpole, had the
'Lacoon' and Bernini's 'Apollo and Daphne' in terra-cotta
by him. He returned to England in 1642, and died in the
same year as his father, as an infant, and his brother saw a
book of drawings by him of many buildings in Italy.

John Stone, the youngest, was also a statuary, though
he was originally designed for the church, and was educated
at Oxford. In the civil wars he entered the King's army;
and narrowly escaped being taken. He concealed himself
for a year in his father's house without his father's knowledge,
and at length contrived to escape to France, where he probably
took to the arts, as he afterwards engaged in partnership with
his brother Henry. He wrote a manual on Fortification,
which he called 'Encliridion;' it contained many small en-
tched by himself, but without his name. He died soon after
the Restoration. In St. Martin's Church, below the inscrip-
tion to Henry Stone, is the following addition, with the date,
June 1869:

*In memory of whom their near kinsman, Charles Stoakes,
repaired this monument."

(Walpole, Anecdotes of Painting in England, &c.)

STORM-SAILS. [Sailes, P. C.] 2

STORMS. [Tornado, F. C.; Whirlwind, P. C.] 2

STORY, JOSEPH, a judge and juridical writer

known to law students as Mr. Justice Story, was born on
the 18th of September, 1779, in Marblehead, in the State
of Massachusetts, U.S. He received the rudiments of learning
in his native town; entered Harvard University in 1798, and
took a degree there in 1800. He commenced his law studies
under Mr. Samuel Putnam; after Mr. Sewall's death, he entered
the bar of Marblehead, subsequently engaged in the chief
justice of Massachusetts, and finally in 1809 he was appointed
under Mr. Putnam, of the bar of Salem, who became a judge of
the same court. In 1801 he was called to the bar, and
speedily obtained extensive practice. In an article in the
Law Review, the author of which enjoyed his friendship,
"it is stated that, 'from political considerations, he was very
early engaged in important causes, in which he had to com-
front the opposition of his political opponents, and, not unfrequently,
sustained the conflict alone.' His reputation at the bar has never been surpassed by that of any of the eminent lawyers of whom the United States can boast. In 1809 he became a member of the State Legis-

lature of Massachusetts, as representative for his district.
He continued a representative until his accession to the bench;
and he then was elected to the office of Speaker. In 1809
he was chosen a member of Congress, as representative of the Knox South District. He acquired a high reputation as a person of sound sense and good judgment. In 1818, he was appointed an Associate Justice of the Supreme Court of the United States. 'The jurisdiction of this court,' says the authority already cited, 'both original and appellate, extends to all cases arising under the said treaties, and the municipal laws of the States, the common, and many of the statute law, as well as the system of equity jurisprudence of England; it had to administer parts of the laws of the Confederate States of America since 1861. It is remarkable that for his eligibility on this occasion he was again indebted to the accident of his being a native of Delaware. He was also elected by the same society a College tutor in the course of the already. In March, William (afterwards Sir William) Jones, who had recently left Oxford for the metropolis. In 1787 he took his master's degree; and in May, 1789, he proceeded B.C.L., having by this time published a volume of Dissertations. He was appointed an advocate at Doctors' Commons. He had already, with a view to the study of the law, entered himself at the Middle Temple, in June, 1789. He was detained at the University however a few years longer than he otherwise would have been by being elected in 1774 by the members of conversation after a contest, to the office of Camden Reader of Antient History. The lectures which he delivered in this capacity attracted crowded audiences and brought him high and wide reputation. It is said that they exist still in manuscript.

At last, in 1776, he retired from the office of College tutor; but he was promoted to the office of Professor of Jurisprudence, and he had taken his degree of D.C.L., which he did in 1779. On this occasion, in the University phrase, he went out grand compounder, which means that he paid the higher fees expected of a graduate. He had saved money from his income as Fellow, and his constantly increasing receipts during the twelve years that he held the office of College tutor; but it is to be remembered that he had also inherited a considerable property from his father who died in 1776. It was probably the independence by which he was thus raised that determined him to resign his employment as a college tutor; but it appears that old Mr. Scott's death was his ruin, for he was stated to be by Mr. Twiss in the first and second editions of his 'Life of Lord Eldon.' He left somewhat less than 20,000l.

He now entered at Doctors' Commons, and passed another year partly in Oxford, partly in London, the rule being that no one shall practise as an advocate till the expiration of that space of time after his admission, which so curiously is called his year of silenct. Dr. Scott was called to the bar in February, 1780. He was admitted into the Faculty of Advocates at Doctors' Commons, according to Mr. Surtees in one place in November, 1779, in another place not till the spring of 1780 (Skeet, pp. 26 and 61). So early however in December, 1778, he had been elected a member of the famous Literary Club, having been mainly indebted for that distinction to the favour of Dr. Johnson, to whom he had been introduced in University College by their common friend, Chancellor Johnstone. Dr. Scott was very popular among literary men. He soon became a favourite with Johnson, whom he had accompanied from Newcastle to Edinburgh, when the latter set out on his tour to the Hebrides, in the autumn of 1772. With the knowledge of Johnson he had become acquainted, and with his qualities, Scott rapidly made his way to distinction in the most intellectual society of the English capital.

His talents and learning, and the reputation he had brought from the University, brought him a large practice in his profession from his first entrance upon it. And his success as an Advocate in no long time led to promotion. In 1785 he was appointed to the office of Registrar of the Court of Faculties. In 1774, the Bishop of London appointed him Judge of the Consistory Court; and the Archbishop of Canterbury, his Vicar-General, or Official Principal. In the same year he was made Advocate-General, and knighted, and was also nominated a Privy Councillor. In 1790 he was nominated by the archbishop Master of the Faculties. Finally, in 1798, he was made Judge of the High Court of Admiralty.

Meanwhile, after having in 1780 been disappointed in his expectation of being sent into parliament as representative of the University of Oxford, and having been unseated on a scrutiny in 1784, when he had been returned for Downend, he had stood in the same time returned for Glos in 1790, through the influence of ministers with the patron, the Earl of Radnor. He was again returned for Downend to the next parliament, which met in 1796. At last in March, 1801, on a vacancy occurring by the retirement...
of their age, are two of the most interesting pictures in the European collections. They were at one time attributed to Houllin, whose works they somewhat resemble; their history is well known, and their present situation is not. They are mentioned in some MS. Annals and Antiquities of Louvain discovered by M. de Bas. The pictures were preserved at Louvain until 1827. They were then sold at Christie's, in the catalogue of the gallery of the King of Holland, the first and second pictures of the Emperor Otho and the Empress Mary. Their subject is from a story of the old chronicles of Louvain, called the Golden Legend, and the event took place 1533. The Emperor Otho III., on his return from a journey to Rome, was condemned at Modena one of his courtiers, an Italian count, to death, in consequence of an accusation from the empress ( widow of a dead husband), that he had attempted her honour. The count was beheaded, but immediately afterwards his widow, with her head on one arm and a red-hot iron which she holds with impurity in her other hand (an infallible proof of her husband's innocence), on her knees Suppliante the emperor for justice. The emperor, being convinced by the fire ordeal of the count's innocence, orders the empress to be burnt at the stake.

From this tradition Stiuerbo painted two pictures for the Town-hall of Louvain in 1468, on wood, each 117 inches French, by 66; the figures are about the size of life. In the first picture the emperor is listening to the false accusation of his wife, the count is being led away to execution; the actual beheading is represented in the distance. In the second picture the widow is kneeling before the emperor with the head of her husband and the red-hot iron in her hands. They are connected by the disconsolate expression of the empress being burnt at the stake; in both pictures are various attendants. The execution is in the style of the Van Eyck school, and is extremely elaborate, especially in the second piece, which represents the emperor by himself.

These pictures were fixed on the wainscoting of the Justicehall at Louvain, and by each was a panel containing an explanation of the subjects in the Flemish language, and in gold letters. They were very directly the fast approach of the decay which, in 1827 they were purchased for a small sum by the late King of Holland, who presented them to the present king, then Prince of Orange. They were removed to, and restored at Brussels, and were in the collection of the Prince of Orange there, until 1841, when they were placed in their present locality at the Hague.

In the above-mentioned MS. 'Annales et Antiquités de Louvain,' it is stated that Dyrik Stiuerbo painted these two pictures for the Council-hall in 1468, and that he was paid for them 236 crowns. In the same MS. it is stated that Stiuerbo was on the 30th of May of the same year commanded by the city to paint 50 pictures 50 by 24 feet, another of the Last Judgement 6 feet high and wide, both for the sum of 500 crowns. What has become of these pictures we know not; they are probably preserved; but if Stiuerbo died in 1470, the last picture would have been probably never painted; the other was completed, and for many years in the Town-hall. Van Mander mentions a picture by Dirk Van Hasselt which he saw at Leyden; in the drawer was the head of Christ, and on two side-wings the heads of St. Peter and St. Paul. It was inscribed as follows in gold letters in Latin— One thousand four hundred and sixty-two years after the birth of Christ, Dirk, who was born at Hasselt, made me at Louvain. Eternal peace abide with him.' From this inscription it is evident that the Dirk of Louvain mentioned by Guidicini in his 'Description de tous les Pays-Bas,' Antwerp, is the same as Dirk Van Hasselt, though that writer mentions them as two painters. Van Mander mentions Dirk de Louvain. Stiuerbo must have resided some time at Louvain. He was also from his style probably a pupil of Jordaen. The subject of some of his school pictures prove that Stiuerbo was a much better painter than many of the most celebrated of his followers; the proportions of his figures are better, his forms fuller and better modelled, and his hands are executed with less rigidity and harshness of feature. M. Nieuwenhuyys and others give 1410 and 1470 as the respective dates of Stiuerbo's birth and death, but how the information is acquired is not stated; Van Mander, who published in 1604, had also acquired this knowledge either. They appear to have originated with Otley, who makes some conjectures on the matter in his 'Early History of Engraving.'

(Passavant, Konstauire durch England und Belgien, etc., Handelshuis, Description de la Galerie des Tableaux de S. M. Le Roi des Pays-Bas, 1840.)

SUCRE, Pierre, a distinguished French painter, was born at Uccle in 1665. His father, who was also a painter, was his first instructor, but at the age of fifteen he took his brother to the Louvre, where he received a good training from a painter of reputation in that part of France. In 1724 he went to Paris, and two years afterwards obtained the grand prize for painting given by the French Academy for a picture of the Battle of Parnassus. In 1727 he was appointed to the charge of the Academy at Rome, with a pension from the then government, and he remained there the remainder of his life, and acquired a great reputation. In 1789 he married a Roman lady, Maria Felice della Valli, who bore him a son distinguished as a painter, and they both for a short time afterwards elected members of the academy of St. Luke. Subleyras was patronized by the pope Clement XII. and Benedict XIV., by several cardinals, and many of the Roman nobility. He painted Benedict's portrait, and was commanded by that pope to execute one of the altarpieces for St. Peters, to be worked in mosaic. The picture, representing St. Basil celebrating mass before the Emperor Valen, who is seated with a flaming St. who was finished in 1746, and after being exposed in St. Peter's for three weeks, was removed to the mosaic offices, and completed in mosaic before the death of Subleyras. He died at Rome of pulmonary consumption, in 1759.

There are several fine pictures by Subleyras in Rome and in some other cities of Italy, and a few in France; there are eight in the Louvre. His execution was delicate, but he composed his pictures to a certain extent on the line, and his portraits are fine, and his heads are drawn with great care. Among the other pictures which are in the Louvre—The Breeze Serpentine at the feet of Christ, and St. Bruno restoring an infant to life. There is also an Holy Family, which is signed by him.

(D'Argenville, Abrégé de la Vie des Peintres, etc.; R. Dumenil, Peintre-Grammair Français.)

SUBULVILLA (from subulalis, an awl), is for the first time mentioned in the 'Historia de la natura et ordine Cruelium et de la tribu Subulare.' It has an oval-oblong internaly compressed pachys, with boat-shaped valves.

S. aquatica, Awl-wort, is a little aquatic starry herb, with fasciculal simple white fibrous roots. The radical leaves are linear and awl-shaped, the scapo naked and few-dowered, the pedicels filiform and bractless. It is native of the colder parts of Europe, in ditches, lakes, and rivulets with a muddy or gravelly bottom. It is also found plentifully in the north of England, Scotland, and Ireland. Sir W. Hooker and Sir J. E. Smith agree in stating that the flowers always remain several feet under water, even during the time they are expanded, so that, other plants may grow to a large size in that element. This curious little plant only requires to be planted or sown in a pond or rivulet, with a sandy bottom, or it may be kept in a pot filled with sand or gravel, and then plunged in water.

(Don, Gardener's Dictionary; Babington, Manual of British Botany; Burnett, Outlines of Botany.)

SUCS. There is a legendary term derived from the Roman 'Successio,' which signifies a coming into the place of another, and Successor is he who comes into such place. The Roman term signifies a coming into the place of another so as to have the same rights and obligations with respect to property which that other had. There might be such a succession either by coming into the place of a living person, or by becoming the successor of one who was dead. Great care must be taken to avoid confusion of the terms. In living, one instance of which is the Bonorum Cessio according to the Lex Julia. Succession was again either Universal or Singular. The instances of Universal succession (per universum) are two: First, the holding by a person's heirs, getting the possession of the bona of another, buying all a man's property, adopting a person by adoptio, and admitting a woman into the manus as a wife; in all of which cases the heaer succeeds in personal possession. Secondly, possession at once to the person who was made heirs, or got the bonorum possession, or bought the whole property, or adopted another by adoption, or married the woman. An instance of singular succession is the taking of a legacy under another's will.

The term Succession is used in our language. We speak of the succession to the crown or the regal dignity, and the term implies that the successor in all things represents the person
cessor. Indeed, the king as a political person, never dies, and upon the natural death of a king the heir immediately succeeds. The English heir-at-law takes the descendible lands of his ancestor as universal successor; and the executor takes the descendible lands of the intestate, and is kept up by a perpetual succession of members, so as to continue for ever. It is true that when members of a corporate body die, others are appointed to fill up their places, but they do not succeed to the same corporate property—a corporation simply becomes members of the corporation. But it has been established in some cases (2 B. & Ad. 840) that the use of the word 'successors' implies that the legislature meant to establish a corporation; and yet it is certain that a feoffment of land to a corporation aggregate without the word 'successors' is a valid grant. In a feoffment to a corporation sole the word 'successors' is necessary. The succession in the case of a corporation sole follows the nature of the Roman succession. In the case of a corporation aggregate there is no succession, and the role that a corporation may be established by the use of the word 'successors' in a statute is founded on an assumption, not a necessity of the word 'successors.'

SUCCESSION, WAR OF, the name usually given to the war occasioned by the succession of the Duke of Anjou, grandson of Louis XIV., to the throne of Spain. Charles II., of Spain, the brother of Louis XIV., to whom he was related without affaditt, having no issue nor brothers, the succession to the Spanish monarchy appeared to belong to Maria Theresa, Queen of France, the eldest sister of Charles, and to the children of her marriage with the Prince of Parma. The marriage was terminated by a solemn covenant her right to the throne of Spain. The second sister of Charles was married to Leopold I., Emperor of Germany, and had not made on marriage a renunciation of her right. The French, however, the Electress of Bavaria, had, previous to her marriage, been obliged to renounce her hereditary claims. The Emperor Leopold in consequence claimed the crown of Spain for his daughter. Two suits were brought, in which the latter was the principal plaintiff. The Electress of Bavaria, on the other hand, maintained that the renunciations alluded to could not prejudice the children, who held their right not by their mother, but by the fundamental law of Spain. Each of these powers endeavored to influence Charles II. in their favor, and he was at length induced to name in his will Joseph Ferdinand, Elector of Bavaria, as his successor. The early death of this prince, in 1699, revived the contending claims of the Houses of Bourbon and Austria.

These different claims having excited the apprehensions of a general war, a treaty, called the second treaty of partition [July 24, 1700], was signed by the French, Spanish, and English, at the Hague, on the 24th of March, 1700, between France, England, and Holland, the details of which will be found in another part of this work. By this treaty the Archduke Charles, son of the Emperor Leopold, was declared to have the right of a son to the Spanish crown. In the meantime the grandson of Louis was awarded the duchy of Lorraine, together with the kingdom of the Two Sicilies and the province of Guipuzcoa in Spain. This treaty however was rejected by the emperor, and the consequences of his rejection proved finally fatal to the cause of his son.

On the death of Charles II. (Nov. 1, 1700) a secret will was discovered which named the Duke of Anjou sole heir to the whole of the Spanish monarchy. Though Charles had been influenced in drawing up this will by the intrigues of Madame de Maintenon, carried on through the Marquis d'Harcourt, who was afterward executed as a traitor to the house of Austria, with Austria at least, must be the issue of his acceptance of the Spanish crown for his grandson, hesitated before availing himself of the offer, which was rendered the more probable by the prolonged and inauspicious course of his father's reign. The title of Philip V.: to his assembled court he presented him with these laconic words:—'You see before you the king of Spain. Nature has formed him for it; the deposed king has none. The death of Charles II. of Spain rendered the title of Philip V. a perpetual succession of members, so as to continue for ever.' It is true that when members of a corporate body die, others are appointed to fill up their places, but they do not succeed to the same corporate property—a corporation simply becomes members of the corporation. But it has been established in some cases (2 B. & Ad. 840) that the use of the word 'successors' implies that the legislature meant to establish a corporation; and yet it is certain that a feoffment of land to a corporation aggregate without the word 'successors' is a valid grant. In a feoffment to a corporation sole the word 'successors' is necessary. The succession in the case of a corporation sole follows the nature of the Roman succession. In the case of a corporation aggregate there is no succession, and the role that a corporation may be established by the use of the word 'successors' is a statute is founded on an assumption, not a necessity of the word 'successors.'
heavily but unsuccessfully disputed by the Bavarians near Donauwörth. Advantage was taken of their success by the allies to offer peace on favourable terms to the elector, if he would withdraw his troops from the Rhine; but the Bavarians, Marchall Tallard with a French army of 30,000 men determined the elector upon refusing these proposals; at the same time Eugene had joined Marlborough with 20,000 men; the Prince of Orange was there with 25,000; and the Spanish force, under whose command they planned, was sent to reduce Ingoldstadt. On the 18th August a decisive engagement took place, which terminated in the complete defeat of the French and Bavarians. The details of this battle are found in the articles BLESSEM and MARLBOROUGH, P. C. This disaster was followed by the loss of Bavaria, which was occupied by the Imperialists, and the elector was compelled to retire with the French army to the frontier (11 September). [MARLBOROUGH, P. C.] The surrender of Munich and the terms of surrender were granted, and a peace was on the eve of being proclaimed when all hope of it was extinguished by a further proposition from the allies, to which it would have been disadvantageous, to the Crown Prince of Saxony, and to take up a position at Brussels. In Italy and Spain the French obtained some advantages, which however were counter-balanced by the loss of the important fortress of Gibraltar, which fell into the hands of the English on the 24th July, 1704. [GIBRALTAR, P. C.] The next year, 1705, the Emperor Leopold died, and was succeeded by his eldest son Joseph, whose character for energy and determination formed a favourable contrast with that of his father. After some hesitation, he decided upon vigorously pursuing the war in support of the claims of his brother Charles, who the year previous had succeeded to the Spanish throne. The war was conducted in Aragon, Catalonia, and Valencia. Nothing however of importance occurred during the campaign of that year; the Prince Eugene was sent to Italy to recognize the army, while Marlborough and Prince of Orange entered Flanders to assist him. In 1706 fresh exertions were made by Louis to maintain an army in Germany, and to take the offensive in Savoy and Flanders. Accordingly he sent into Flanders one of the finest armies that had yet appeared in the war, and placed it under the command of Marshal Villeroi. The impudent air which this general preserved disgraced his projects; he left a strong position which he had taken up at Louvain to give thanks to God on the spot, and abandoned it, which resulted in his complete defeat. [RAMILIES, P. C.] The details of this great battle will be found in the article referred to; but the fact that it was fought almost on the site of Waterloo, by which name it has often been designated, may not perhaps be generally known. The victory at Ramilie Secured to the allies the greater part of the Spanish Netherlands, while, to increase the misfortunes of Louis, his Marshal, Marignan, lost the battle of Turin against Prince Eugene (September 7); a defeat which was followed by the loss of all territories which had been occupied by the French in Italy. [EUGENE, P. C. ] In Spain they were also repulsed in Catalonia, and the Portuguese, under Prince of Condado, entered Madrid, which city however they were unable to retain. At this juncture of affairs a suspension of hostilities was proposed by Louis to the allies, but rejected chiefly through the influence of the pensionary Antony Heinsius. In 1707 a considerable portion of the Spanish inheritance was in the possession of the Imperialists and the allies, while Lombardy and Flanders had already been secured to them by the battles of Turin and Ramilie. Louis at this time determined upon a diversion in his plan of attack, which was soon followed by important consequences. The large body of troops which had been forced to evacuate Italy he collected together, and, placing them under the command of the Duke of Berwick (Berwick, James Fitz-James, Duke of, P. C.), sent them to Catalonia in support of his grandson. On the 24th April a most decisive victory was obtained by him over the English and Portuguese under the Earl of Galway and the Marquis Los Minas at Almansa. In this important battle the Spanish sustained a loss of 17,000 killed, wounded, and taken prisoners; their two generals were withdrawn from the field severely wounded, and 120 standards fell into the hands of the French. The victory of Almansa proved the turning point of the war, which, from that time to the close of his cause, finally ensured the throne of Spain to Philip V. Aragon and Valencia were reduced to his submission by the Duke of Orleans, and in the latter end of the year 1707 the only forces which were maintained by the enemy were those in Catalonia. The following year Prince Eugene once more formed a junction of his forces with those of Marlborough, and thus united gave battle to the French army under the command of the Prince of Burgundy and Vendome at Oude-
of Marlborough of his influence; measures of peace were simultaneously taken. [Auchter] P. C. was set on foot between the Courts of England and France, which ended in a preliminary treaty of peace being signed in London on October 6, 1711. The conferences for a general peace at Utrecht were selected at the place where they were to be held.

The negotiations which took place at Utrecht in the early part of the year 1719 met with several interruptions, arising from the everlasting interests of the different powers who composed the grand alliance. The victory obtained by Marshal Villars over the Earl of Albermarle at Denain (24th July, 1719) [Villars, P. C.], and the consequent recovery of Dunkirk, was an aristocratic rule which restored the French, and rendered the allies more tractable. Peace was at length signed at Utrecht in the month of April, 1718, between France and England, the United Provinces, Prussia, Portugal, and Savoy; the Emperor alone refused to take part in it. A full detail of the terms of that treaty will be found in another part of this work (I. C. vol. xxv. p. 174).

The real gain by it was undoubtedly the French King, who obtained nearly all the advantages which it had been the object of the war to prevent his acquiring; it was also productive of considerable odium against the English ministry.

Disasters which now deserted by his allies, was compelled to negotiate alone a peace, which became important even for the security of his hereditary states. It was brought about by the moderation of the two great generals Eugene and Villars, and by the drudgery of Joubert's staff. In the war, proved themselves the most desirous of promoting peace. They commenced negotiations at the Castle of Raisins in November, 1718, and a treaty was there concluded on the 7th March, 1719 (Joubert, P. C.); and the terms of it were definitely agreed upon on the 7th September following at Baden in Aargau. [BADEN, TREATY OF, P. C. vol. xxv. p. 174.] The King of Spain acceded to these treaties, and England agreed to the peace.

For a more detailed account of this war, the following works may be referred to: Koch's 'Revolutions of Europe,' translated by Crichton, 5 vols., Edinburgh, 1825, vol. ii. p. 145-157; *Outlines of History;* Lorden's 'Cabinet Cyclopædia,' p. 584-590; Kohrmann's 'History of Germany,' translated by Hass, London, 1844, p. 632-647; Schlosser's 'History of Europe,' vol. iii. p. 17-84, translated by Davison, London, 1844; 'History of Spain,' Library of Useful Knowledge, London, 1833, book iii. chap. 1, 2, 3; Voltaire, 'Essai sur l'Histoire Générale,' &c., chap. 190-196; Lord Mahon, 'History of the War of Succession in Spain.'

[French: [MASSÉNA, P. C.] of Albufera and Marshal of France, was a native of Lyons, where his father was a silk manufacturer. The year of his birth is stated by some authorities to have been 1770, by others 1772. On the battle of Toulon, in 1793, he was distinguished as a lieutenant in the cavalry of the national guard of Lyons; shortly afterwards, he became captain of a volunteer company raised in the department of the Arzbehe, which he commanded during four years, and during which he procured the 'bataillon' in the troops of the above-named department. In his capacity, it is stated, he was compelled to be the active witness of many atrocities, committed in the name of the law by the depôt of the convention, Maingret. He was present at the siege of Toulon in 1793; from thence he was transferred to the army of Italy, and was attached to the brigade under the command of General Larue. In this campaign he specially distinguished himself at the combat of Lomont (23rd November, 1795), where he captured three Austrian standards. He afterwards served with distinction in the same campaign under the Generals Augeperse [Augeperse, P. C.], and Masséna [Masséna, P. C.], and received several wounds. He was selected by Masséna to present to Bonaparte the standards which he had captured during the year 1799 by the brigade in which he was battalion. It was on the field of battle of Neumark (2nd April, 1797) that he was raised to the rank of chef de bataigne. He afterwards joined the army in Switzerland, where he was instrumental to the conclusion of a treaty with the cantons of Berne and Berne, which stopped the advance of the French, and after rekindled in Switzerland, and in it Souchet displayed considerable skill; it was there that he first gave proof of his talents as a tactician, which afterwards raised him so high in the estimation of the French, and in which he was recognized by his chief, who deputed him to Paris to present to the Directory twenty-three standards taken from the Austrians.

When the expedition to Egypt was determined upon, it was originally intended that Suchet should be included among the military commanders selected to act under Bonaparte; he was, however, on account of discipline, dismissed from the army of Italy, and the representations of General Brune, who commanded it, caused him to be retained there with the rank of Major-General of Brigade. In his new position he made many strenuous endeavours to renew the ancient discipline and to anesthetize the condition of the soldier; these endeavors were construed by the suspicious government at Paris into an attempt to introduce in the army of Italy the principles of discipline which he had been desirous of applying to the strong remonstrances made on the subject by General Joubert, who was among the most popular and successful of the republican generals of that period. On his arrival at Paris, he succeeded in clearing himself of the charges which had been brought against him, and he was transferred to a command in the army of the Danube. He there rendered himself conspicuous by the able manner in which he seconded the skilful marshals of General Masséna in the Grisons. [Masséna, P. C. S.] The successes which attended the French arms in Switzerland were counter-balanced by the disasters of General Schérer in Italy; these disasters necessitated the appointment of a more active and vigorous commander, and Joubert was again intrusted with the chief command. On this occasion Suchet was recalled from the army of the Danube, and placed at the head of the main army, a post which he succeeded in filling to his military reputation; the careful avoidance of error in his movements and manoeuvres, the skilful disposition of his troops, whether attacking or in conjunction with the main army, as he procured him important success, soon attracted the notice of Bonaparte when he joined the Italian army, and he was appointed by him second in command to Masséna. In this capacity he particularly distinguished himself at Aix-la-Chapelle, in the battle of Cezio (7th and 8th May, 1800). With a body of eight thousand men, advantageously posted, he checked the advance of General Mélas, who had five times his numbers, and, for a long time harassed his army, when he had cut off; he thus afforded a powerful co-operation to the main army of the French, which, under the command of Bonaparte, was at that time crossing the Great St. Bernard. [Bonaparte, P. C.] General Suchet, after these operations, rejoined Masséna on the plains of Alessandria, and was present at the battle of Marengo. When, in consequence of this decisive battle, the city of Genoa again fell into the hands of the French, he enjoyed the position of a great in this campaign.
ally contributed to the success obtained by Savary, Duke of Horigo, over the Russian General Essen, who, with twenty-five thousand men, attacked the French on the banks of the river Narro (16th February, 1807), and was repelled with considerable loss.

The reputation which Suchet had acquired in these engagements, as a brave soldier and a skilful tactician, induced Napoleon to intrust him with a separate command. An opportune moment had arrived to afford him by this means a test of his abilities. Suchet had been left behind the lines in Spain in 1808, and he gave him the command of the fifth division of the army, having previously raised him to the highest grade of the Legion of Honour (Legion or Honour, P. C.), and having bestowed upon him the generous gift of 20,000 francs, with which he purchased a seat in the Imperial Court of the Empire. After assisting for a short time at the siege of Saragossa [Saragossa, P. C.; Lannac, P. C.S.], he was appointed to the important command of general-in-chief of the Spanish army in the province of Aragon. This brings us to the most illustrious period of this general's military life; the campaigns which followed under his command, are among the most brilliant recorded in history, and it is to be regretted that sufficient justice has not been rendered to his merit by the English annalists of this war, previous to the time of General Napier. To this distinguished and impartial historian has been reserved the honourable task of raising the character of an enemy to the position he deserves in public estimation. When General Suchet was placed at the head of the forces in Aragon, he found the army so destitute of discipline that it almost amounted to disintegration; but he perceived that he could reform this discipline, he evinced considerable discernment, prudence, and energy; no longer thwarted in his efforts by the factions opposed to mere theoretical statesmen, was he dismayed by the time which he thought the army was necessary to Jutice and vigour. Indeed, he was specially equipped for this important purpose. Suchet, says the historian above referred to, 'was no ordinary man; and with equal vigour and unswerving determination he commenced a system of discipline in his corps, and of order in his government, that afterwards carried him, with scarcely a check, from one success to another, until he obtained the rank of marshal for himself, and the honour for the corps of being the only one in Spain that never suffered any signal defeat.' (Napier. History of the Peninsular War, vol. ii. p. 97.) In 1810 General Suchet received orders from Madrid to lay siege to the strong fortress of Lerida, the approaches to which were covered by the Spanish General O'Donnell and a strong body of Catalan troops. The defeat of this general was followed, after a gallant and obstinate resistance, by the surrender of the fortress which he had protected (14th May, 1810), in which were found five hundred pieces of artillery. The fall of Lerida was followed by that of Macauquilas (8th June, 1810), and Tortosa (2nd January, 1811). These successes were followed by one still more important, the taking of the city of Tarragona (17th December, 1810), of which was defended by a garrison of eighteen thousand men; the city fell into the hands of the French after a siege of two months, or rather, as Suchet himself expressed it, after a succession of three sieges and five assaults. The army of the French consisted of some five thousand cannon and abundant munitions. (Tarragona, P. C.)

The sagacity of Suchet in the siege of Tarragona proved itself; from the fact that upwards of nine thousand Spaniards of the garrison are said to have perished. The occupation of Mont-Serrat, a place of such great strength that it was deemed unserviceable, followed soon after the capture of Tarragona. These brilliant services were most appreciatively appreciated by Napoleon, who rewarded them by raising Suchet to the dignity of a Marshal of the Empire. In the latter end of the year 1811 Suchet directed the operations of his army against Murviedro, the ancient Saguntum [Lannac, P. C.], the fortifications of which had been reconstructed by the French after the defeat of General Blake and thirty thousand men under its walls, was, followed, after about a month's siege, by the fall of this important fortress. A reinforcement of fresh troops having arrived in Aragon, Suchet succeeded in investing the city of Valencia, which surrendered to him by capitulation on 10th January, 1812. The fall of this city, and of some fortresses in its neighbourhood, was followed by the occupation of the entire province of which it was the capital. Although this province, which had been the scene of his last successes, became the title of the dukedom which he was made by Napoleon, who added to this title an extensive and valuable domain. But he had little time to enjoy his conquests; the Spanish stations were not at present occupied with this reflection and admiration of posteriority by the general expressed feeling of the Spaniards under his rule, that he mitigated the horrors of war by his humanity, and dealt equal justice to the conquered and to the conquered. 'The mission imposed upon him had been to conquer and to subdue; he was required to provide for the expenses of the war by the successes of war; the mission, however, which he imposed upon himself was to augment the power of Spain, to increase the number of her vassals, and to diminish her enemies. (Translated from Le Journal de la Méditerranée, 7th January, 1826.) Marshal Suchet pursued the same system of government in the province of Valencia that had answered so well in Aragon; he placed in the hands of a corps composed of enlightened and respectable men. He called together an assembly of persons of every class of society, and who represented various interests, to vote the expressions of the will of the people on the war and peace of the province, and the arrangement of the public finances. He induced a faithful and detailed account of the manner in which these taxes were employed. He manifested the same spirit of confidence and justice towards the soldiers under his command, and found it productive of the most beneficial results.'

The success which attended the British arms under Lord Wellington, and the decisive victory which he obtained at Vitoria, compelled a large portion of the French army to retreat beyond the Pyrenees, and, in consequence, Suchet found himself under the necessity of abandoning the eastern provinces of Spain, and to fall back upon Catalonia, where he maintained himself for some time. Ordered at length to evacuate this province, and to retreat towards the frontiers of France, he effected this retreat in the attitude of a conqueror, and with such skill, that the movements rarely found unexpected on such an operation. On reaching Narbonne, 14th April, 1814, his adherence to the decrees of the senate directed against Napoleon. Employed to receive Ferdinand VII. of Spain, 5th P. C., he was released from Valencia, and to present him to the Spanish army, he was publicly thanked by the king for the manner in which he had carried on the war against his subjects. The gratitude of the Spanish nation towards the administration of this marshal will be further evinced by the general testimony which was borne to his justice and humanity, when, in 1823, the French again occupied the scene of his exploits. The correct view taken by Suchet, with respect to the return of Ferdinand, will be seen by reference to Monholon, History of the Captivity of Napoleon, vol. ii. p. 350.

The speedy adherence of Suchet to the Bourbon was rewarded by his being created a member of the new peerage, and his appointment to the command of the tenth military division, of which the head-quarters was Strasburg. On the return of Napoleon from Elba, though he unmitigated his fidelity to the Bourbon, at a long council in France, he renewed his allegiance to his former chief, and accepted the command of the army of the Alps, with which he obtained several important successes over the Piedmontese and the Austrians, and the capture of forty thousand men, and on the approach of the main body of the Austrians, nearly one hundred thousand strong, he was compelled to fall back upon Lyon, for which city, by his judicious management, he obtained the title of Marshal. Such was the condition in it being that all the valuable mentions of war contained in that city should be respected by the enemy.

On the second restoration of the Bourbons, he remained for some time in disgrace, and was deprived of his civil though not of his military honours. He was however restored to his position in the peacetime by a royal ordinance, dated the 6th of March, 1819. That he entirely recovered the favour of the king may be presumed from the fact that he was chosen to assist at the birth of the present Duke of Bordeaux. On the French expedition to Spain, in 1823, it was generally expected that Marshal Suchet would have been selected to accompany the Duke of Angoulême, as his principal adviser, but he was already suffering severely from the disease to which he shortly afterwards fell a victim. He died at Madrid, 1829. His widow, the Marchioness giving behind him a young widow and several children. During the latter years of his life he was occupied in composing a memoir of his campaign in Spain, which has since been published. (Milnor, Historical Dictionary of the French Revolution, vol. ii. p. 71.)
S U R

The reputation of Susaet stands deservedly high amongst the generals of Napoleon. His military career was sustained by many of the excursions which have disgraced so many of his most distinguished colleagues in command. Brought up in the household of M. de Tarragon, a rich and influential member of the nation, Napoleon was committed by our own army at Badajos and St. Sebastian, and it would be unjust to throw the odium of them on his illustrious commander. The inability of a chief perfectly to restrain the frenzied violence of his soldiers on such melancholy occasions is a melancholy fact which the history of all ages has established. They have already dwelt upon his qualities as a military and a civil ruler.

The high opinion entertained of Susaet by Napoleon has been almost universally subscribed to. Louis Carbon, the questioner being asked him by the former, who, in his opinion, was the first of his generals? he replied, 'I think that Susaet is probably the first. Masona was; but you may say that he is dead' (1817), alluding to the complaint under which that man was fast sinking. On another occasion, at St. Hilaire, Napoleon remarked, 'that if he had had two such field-marshals as Susaet in Spain, he should not only have conquered, but kept the Peninsula. His sound judgment, his governing yet conciliating spirit, his military tact, and his bravery had procured him astonishing success.' (Court and Camp of Bonaparte, p. 410.)

SULPHUR, or SULPHURING, is the process of bleaching employed to give whiteness to silk and woollens by exposing them to the fumes of burning sulphur. For this process a detached chamber, without a chimney, is made use of, but so constructed that, when required, a current of air may be passed through it.

According to Berthollet, 100 pounds of alkali, strewn on perches, are placed at a height of nearly seven feet, and about two pounds of sulphur, reduced to coarse powder, are put into an iron pot, containing a small quantity of ashes; the sulphur is fired in several places, and the chamber well closed to prevent the escape of the fumes. The windows are opened to let them escape and to dry the alkali. In winter, after the smell of the sulphurous vapour has ceased, the windows are shut, and charcoal is burnt in the chamber, in order to dry the alkali. By this process, the silk becomes perfectly white, and is rendered fit for subsequent operations. Woollen cloths are treated nearly in the same manner.

SUMMARY CONVICTION. [Law, Criminal, P. C. S.]

SUMMER. [Winter, Spring, Summer, and Autumn, P. C. S.]

SUPERCARGO. [Ships, P. C. S.]

SURFACE OF ELECTRICITY. [Polarization of Light, P. C. S. p. 330.]

SURGEONS, COLLEGE OF. [Surgeons, College of, or, P. C. S.]

A new charter was granted to the College of Surgeons in the 7th year of Victoria, by which it is declared that the name of the college shall henceforth be "The Royal College of Surgeons of England; and that a portion of the members of the said college shall be fellows thereof, by the name of The Fellows of the Royal College of Surgeons of England." The charter declares that the present president and two vice-presidents, and all other the present members of the said college shall be fellows thereof, and such other persons, not being less than 250 nor more than 300, and being members of the said college, as the council of the college, at any time before the expiration of three calendar months from the date of the said charter shall appoint in manner by the charter authorized, shall be fellows of the said college. But no person, except as hereinbefore named, is to become a fellow unless he shall have attained the age of twenty-five years, and conformed with such rules as the council of the college shall think fit and by a by-law or by-laws direct; nor unless he shall have passed a special examination by the examiners of the said college. Every person admitted as a fellow, as he is a member of the College by such admission, if he is not already a member.

Henceforth no member of the College who is not a fellow shall hold any office or be eligible to any office of the College. There are also 10 (some other restrictions as to eligibility as the present members of the council are to continue life members as herebefore, and the number of members of council is to be increased from twenty-one to twenty-four, members of the council are to be elective, and to be elected periodically, in the manner prescribed by the charter (12) when the number of elective members of the council shall be completed and made up to twenty-four. Three members shall go out annually, but they may be re-elected immediately. The members of council are to be elected by the fellows, including the members of the council as such, in the manner prescribed by the charter (15); and the election is to be by ballot (17). There are various special provisions as to the eligibility of fellows, for which we refer to the charter. There are to be ten examiners of surgeons for the college, and the present examiners are to continue the office for an indefinite time, and all future examiners shall be elected by the council, either from the members of the council or from the other fellows of the college, or from both of them; and all future examiners of the College shall hold their office during the pleasure of the council. The charter contains other regulations, and provides the powers of the college and the council, except as far as they are altered by the charter; and it declares that no by-law or ordinance hereafter be made by the council that shall be any force until the same shall have signified its approval thereof to the College under the hand of one of the principal secretaries of state, or otherwise as in the charter stated (22). For the examination of candidates for the fellowship (sect. 1), for the admission of candidates for the fellowship (2), admission of fellows (5), election of members of council (6). By section 1 it is required that every candidate for the fellowship, among other certificates, shall produce a certificate, satisfactory to the court of examiners, that he has attained a competent knowledge of the Greek, Latin, and French languages, and of the elements of mathematics. The subject of examination for the fellowship are Anatomy and Physiological on the first day, and Pathology and Therapeutics and Surgery on the second day. The examination is to be by written answers and oral examination; the latter part of each candidate may be interrogated by the examiners, on any matter connected with the questions or answers. In the anatomical examination the candidate must also perform dissections and operations on the dead body in the presence of the examiners.

The members of the College are admitted by diploma after examination before the court of examiners, and their diplomas confer upon them the right of practising surgery in any part of the British dominions.

The council of the College have at various times required certain qualifications of age, education, &c. from candidates for examination. The regulations last issued are dated October, 1841.

The examinations of members are conducted twice yearly, or, if the candidate desire it, in writing. The questions are almost exclusively anatomical and surgical; and the examination of each candidate occupies about an hour and a half, during which time he is usually questioned by four of the examiners in succession.

According to the financial statement (June, 1845), the receipts of the College for the previous year were as follows:

\[
\begin{align*}
\text{Court of examiners: fees for diplomas, &c.} & = 2,500,000 \\
\text{20 guineas each, exclusive of stamps} & = 4,092,110 \\
\text{Rent} & = 12,10 \\
\text{Incidental sale of lists, catalogues, &c.} & = 100,66 \\
\text{Expenses on the investments in government securities, &c.} & = 1,400,04 \\
\end{align*}
\]

\[\text{Total receipts:} \quad 21,765,710\]
And the disbursements were as follows:—

**Sussex, Augustus Frederic, Duke of.** A Prince of the United Kingdom, the sixth son of George III., was born on 15th January, 1773. After spending some time under a private tutor, he travelled abroad, and studied at Göttingen. From an incident connected with his early history, a very curious question regarding the law of marriage and legitimacy arose. In April, 1798, he was privately married at Rome to the Lady Augusta Murray, daughter of the Earl of Dummore. Independently of other questions, it was thought that there might be an objection to the validity of this marriage on the ground that its being celebrated by a Protestant clergyman in a place where by the law of the state a marriage by such a person is invalid, and where there was no British representative of the Anglican Church. Accordingly the ceremony was repeated in St. George's, Hanover Square, London, on 5th December, 1798. The ground for questioning the validity of their union was the Royal Marriage Act of Geo. III. c. 13, which prohibits every descendant of George III. from contracting matrimony without the consent of the crown, and provides that every marriage contracted without this consent being first obtained, shall be null and void to all intents and purposes what-so-ever. There is no doubt that, so far as respected England, the English marriage came under this act. But there were reasons for supposing that the marriage at Rome might be capable of being declared valid in other parts of the kingdom, of which the Duke, as a prince of the blood, was as much a citizen as he was of England. With regard to Scotland, the statute was so much connected with the English Marriage Act, that it is questioned if it extends to that part of the kingdom; and as to Ireland, that country was not united to England when the act passed. It was supposed that the question might come to be considered in relation to the succession of the throne of Hanover, but the birth of a nearer heir has rendered such an event unlikely. His first wife having died in 1834, he married in 1840 the widow of Sir George Buggin, without conforming with the Marriage Act. On 20th November, 1830, he became President, after a pretty warm contest, of the Royal Society, but he resigned this office before his death. He was a great friend of literature and art, and a warm supporter of every liberal measure in politics. He was of a popular, easy disposition, and he was a great collector of rare books, and left behind him a magnificent library. It consisted in 1827 of 50,000 volumes, 14,000 of which were theological. He died at Kennington Palace on 21st April, 1849, and was buried in Kensal Green Cemetery.

(Biographical Dictionary of the Society for the Diffusion of Useful Knowledge.)

**Sustermans, Justus,** a distinguished Flemish painter, was born at Antwerp in 1597. He was the pupil of William de Vos. He is little known in Flanders; he lived chiefly in Florence, where he was appointed his court painter by the Grand-Duke Cosmo II. He was favoured also by Ferdinand II., whose portrait he painted, and who ennobled him. His master-piece is a large picture of the Florentine nobility wearing allegiance to Ferdinand upon his succession. He died in 1681. There are several portraits of him in the Pitti Palace at Florence. Rubens is said to have pronounced Sustermans an honour to his country.

(_Descamps, La Vie de Peintres Flamands, &c._; Lanz, _Storia P. D._, &c._)

**SWIFTEST PROPAGATION, PRINCIPLE OF, in the undulatory theory of light, is the expression of the fact that the front of a wave, after reflection or refraction, passes through a given space in the least possible time; the velocity after refraction being the same as before, and after refraction being that which depends on the medium in which it waves.

In the article "Undulatory Theory, P. C.," the equality of the angles of incidence and refraction was proved only for the case in which the reflecting surface is a plane; but it is easy to prove that the equality subsists whatever be the form of the reflecting surface. Let $N Q S$ be a section through the axis of a reflecting surface, and $\therefore$ the radiant point be infinitely remote, let $MN, PQ, RS$ be rays of right, or lines parallel to the direction of the incident wave; or, if the radiant point be at a finite distance, let these lines diverge from such point so that in either case they may be perpendicular to the general front of the wave: also let that front have the position $nS$ at a certain time if the reflecting surface be not interposed. Then $N, Q, S$ being the centres of the partial waves produced by reflection, let the curve at $n'$ be part of the surface of the wave originating at $N$; its radius $Nn'$ being equal to $Nn$, since the velocity before and after reflection is the same; and let the curve at $q'$ be the surface of the wave originating at $Q$, so that $Qq' = Qq$. Imagine partial waves to be formed in like manner from every point in the curve surface $N Q S$; then a curve surface touching all the spheres, as at $n$ and $q'$, will be the general surface of the reflected wave, at the time that the surface of the direct wave would have been at $nS$. Next, imagine $Q$ to be very near $N$, and let fall $Qq$, $Qq'$, perpendicular respectively to $Nn$ and $Nn'$; then $Nn'$ may be considered as the difference between $Nn$ and $Qq'$, and $Nn'$ as the difference between $Nn$ and $Qq$; therefore these differences are equal to one another; hence, $N Q$ being considered as part of a straight line touching the curve $N Q S$ at $N$, the angle $QnN'$ is equal to $QnN$ or $MNT$; consequently the angle of refraction (the complement of $QnN$) is equal to the complement of $MNT$, or the angle of incidence.

Again, in the article "Undulatory Theory, P. C.," it is proved that, when light is refracted at a plane surface, the sine of the angle of incidence is to the sine of the angle of refraction in a constant ratio, which is that of the velocities of the waves previously and subsequently to the moment of incidence, and the same law may be proved to hold good whatever be the form of the reflecting surface.

For let $NQ$ be a section through the axis of a transparent medium bounded by a curve surface, and let $MN, PQ, RS$ be rays or lines perpendicular to the surface of a general wave; also let $S_1 q_1$ represent the position of that surface at a certain time if the refracting medium be not interposed. Next, $N, Q, S$ being the centres of refracted waves, let $Qn$ be the surface of such waves at the same time, and imagine half waves to be formed in like manner from every point in the curve surface $N Q S$; then a curve surface represented by $S_1 q_1$ touching all those spherical surfaces will be the general surface of the refracted wave.

Now $I$ and $R$ representing the velocities of the incident and refracted waves respectively, by the principles of the undulatory theory we shall have

$$ I : R :: Nn : Nn' = \left( \frac{R}{T} \right) $$

and

$$ I : R :: Qq' = \left( \frac{R}{Qq'} \right) $$

Fig. 1.
S W I

Next, imagining Q to be very near N, let fall QP perpendicularly on Nn, and Qr perpendicularly on Nr; then:

\[ \frac{Nn}{Qr} = \frac{Nt}{Qr} \]

and, substituting the values of Nn and Qt,

\[ Nt \times Qr = Nn \times Qr \]

therefore

\[ Nn : Nt : Qr : Qr \]

Now NQ being considered as a straight line, it is a common hypotenuse to the right-angled triangles NQn and NQt; hence

\[ Nv : Nt : sin. NQn : sin. NQt \]

But ZQ and Zn being perpendicularly to the refracting surface, NQn is the complement of PQN, and is therefore equal to the angle NnQ. Qr is the complement of QnN, and is therefore equal to the angle (ZnN) of refraction at N—thus

\[ Nn : Nt : sin. of incidence : sin. of refraction ; and it follows that \]

\[ Nn : Nt \]

or, since by the principles of the undulatory theory, the ratio of \( P \) to \( R \) is constant in the same medium, the sine of incidence bears a constant ratio to the sine of refraction.

It may now be shown that a wave is propagated from the distant point to any other point in the line of its direction, subsequently to reflection or refraction, in the least possible time.

Assuming, with respect to refraction, if the waves diverging from N and Q (Fig. 1) with velocities equal to that of the incident waves to take any other directions than those of Nn and Qt, which are perpendicular to the front Sfgr of the general wave, it is evident that they must be reflected through S and touching the surfaces of the several waves would fall between Snw and SN: such surface would then be the front of the refracted wave; and thus the front would, in a given time, have passed through a less interval from the reflecting surface (or from the distant point) than it actually passes through in consequence of the partial waves taking the directions Nn and Qt.

In like manner with respect to refraction: if the waves diverging from N and Q, with velocities which bear to the velocities before refraction the ratio of R to \( P \) to I were to take any other directions than those of Nn and Qt, it is evident that a curve surface passing through S and touching the surfaces of the several waves would fall between Snw and SN: such surface would be the front of the refracted wave; and the conclusion corresponds to that which has been stated for a refracted wave. Therefore in both cases the time, reckoning from the moment of setting out from the distant point, or from the reflecting or refracting surface, during which the general wave arrives in any given position, as Srfg, will be the least possible.

William of Malmesbury, the Bishop of Winchester, was born in the early part of the ninth century, but the exact year is not ascertained. He was ordained priest in 880 by Helman, Bishop of Winchester, and was soon after appointed by the same prelate to be his chaplain. In the reign of the latter he became chancellor, and was intrusted with the education of Alfred, whom he accompanied to Rome. [ALFRED, P. C.] The services rendered by Swin will be bestowed on the cathedral church of Winchester, and the affairs of his kingdom were rewarded by his elevation in 852 to the see of Winchester, vacant by the death of Helman. He is supposed to have been the originator of the payment of ‘Peter-pence’ to Rome, though there is much reason to believe that this tribute had an earlier origin [PETER-PENCE, P. C.], and also to have procured the first act of the Witenagemot for enforcing the universal payment of tithes.

Poulett Thomson, Lord, was the son of John Poulett Thomson, Esq., of Waverley Abbey and Rochampton in Surrey, the head of the mercantile firm of J. Thomson, T. Bonar, and Co., which had been long one of the most eminent houses engaged in the Russian trade. Mr. John Thomson, who assumed the name of Poulett by sign-manual, in 1820, in memory of his mother, married, in 1781, Charlotte, daughter of Dr. Jacob of Felsham, and by her he had a family of nine children, of whom the subject of the present notice, born at Waverley on the 13th of September, 1799, was the youngest. There were two elder sons, Andrew and George, of whom the latter, now George Poulett Scrope, Esq., is the present master of Stroud, and the author of ‘Principles of Political Economy,’ 12mo., 1833, and of ‘The Life of Lord Sydenham,’ 8vo., 1843.

Charles is stated by his brother to have been remarkable in his infancy for his grace and beauty; but the story which he tells of the child, who had attracted the notice of George III. at Weymouth, in the summer of 1803, having been born in the early part of the reign of Mr. Pitt, is not quite correct in all respects; for Mr. Pitt was not then prime minister, as assumed, and could not have been in attendance upon the king in that capacity. It seems unlikely indeed that a child could have been associated with the prime minister, from his native county, at the age of sixteen, to be placed in his father’s house of business at St. Petersberg, then under the direction of Mr. Pitt himself, who was a man of much more serious stamp.

Lord Sydenham was never at any public school or university; and he left his native country at the age of sixteen, to be placed in his father’s house of business at St. Petersberg, thus under the direction of Mr. Pitt himself. He returned to England in ill-health in 1817; then made a tour to the south of France, Switzerland, and Italy; after which he took his place in his father’s counting-house in London, in the summer of 1819. In the spring of 1821 he was again sent out to St. Petersberg, this time as a partner in the firm; and here he remained for two years. The greater part of the winter and spring of 1823-4 he spent in Vienna; whence returning by Paris to England, he assumed, in conjunction with his brother Andrew, the chief conduct of the business in London.

Sydenham, ambitious, and self-confident, he involved himself to some extent in the American mining speculations of 1825. Meanwhile he had become intimate with the late Mr. Bentham and Mr. James Mill, with Mr. Warburton, Mr. Hume, Dr. Bowling, and Mr. McCulloch, and he set his heart upon entering public life. He obtained a seat in parliament for Dover, after an expensive contest, at the general election in the summer of 1826. His rise from this date was very rapid; steadily with the expenses of the Opposition, he spoke lest gendy, and almost exclusively upon commercial questions. On the first occasion however on which he delivered himself at any length, in a debate on the state of corn, in the House of Commons on May 22nd, 1827, he made a very favourable impression on the House, and had the gratification of being warmly complimented.

Saint Swithin’s day, ye gods, do me nae.
For forty days it will remain;

Swithin’s day, ye gods, do me nae.
For forty days tae rain use ma.</doc>
by Mr. Huskisson. After this, whenever he rose he was listened to with attention. He was again returned for Dover in 1830; and when the Whigs came into power, in November of that year, he was appointed to the Post of Vice-Admiral of the Board of Trade and Treasurer of the Navy. He was returned again for Dover after his acceptance of office, and also to the succeeding parliament, which met in June, 1831. At the dissolution in December, he was returned both for Dover and for Manchester; he elected to sit for the latter place; and continued to represent Manchester as long as he remained in the House of Commons. Meanwhile on the reestablishment of the ministry in June, 1832, on the accession to the succession of Lord Stanley and Sir James Graham, Mr. Poulett Thomson was made President of the Board of Trade, in the room of Lord Auckland, who was removed to the Admiralty; and on the recovery of power by the party in April, 1835, after Sir Robert Peel's short administration, he resumed that office with a seat in the cabinet. So early as in the beginning of the year 1836, if there be no misprint of the date in Mr. P. Scrope's narrative, it had been in contemptuation to remove him to the House of Lords, in order to relieve him from the fatigues of the long night sittings in the Commons, under which his health was already beginning to break down; but circumstances, it is said, for a time put a stop to this plan. At last, towards the close of the session of 1839, on the elevation of Mr. Stanhope Rice to the peerage, he was offered his choice between the chancellorship of the exchequer or the government office for Canada; and accepted the latter. He was sworn into his new office before the Privy Council on the 29th of August; he attended the first session of the year, the 15th of September, and the Lord Lieutenant of Quebec on the 19th of October. Of his administration in Canada, which was highly successful, Mr. Scrope has published a very full narrative, which was drawn up by Mr. Murchison, the civil secretary. In August, 1840, the government was raised to the peerage by the title of Baron Sydenham, of Sydenham, in Kent, and Toronto, in Canada. But on the 4th of September, 1841, while in a weak state of health, he had the misfortune to be thrown from his horse, which stumbled and fell upon him, and to sustain a fracture of the principal bone of his right leg, beside other serious injuries; and his death followed on Sunday the 19th of the same month. The most remarkable quality that Lord Sydenham possessed was that great decision of character, arising from clear-headedness and self-reliance. His activity, zeal, and extensive information also made him an excellent man of business, and his very attractive manners added to his value as a partisan. (Memoir, by G. Poulett Scrope, Esq., M.P.)

SYLVESTER, JOSHUA, was born in 1693. He appears to have been of considerable patronage, and was a member of the company of merchant-adventurers at Stade, for whose secretarieship he was a candidate in 1597, recommended by the Earl of Essex. He seems to have always remained a poor man, and spent much of his time in courting the acquaintance of the rich. In the latter part of his life he emigrated to Holland, and died at Middelburg in 1698. Both in his opinions and in his choice of friends he was a most exquisite parodist; and those numerous versified works, chiefly translations from the ancient, on which he exerted his literary reputation, show a warmy devotion and serious tone of feeling. He was not however remiss in courting the patronage of the great. To King James VI. he addressed many salutary dedications; and it was probably in compliment to him that he selected the title of one of his original poems, which is thus entitled: "Tobacco battered, and the Pipes shattered (about the Earl that idly idolize so base and barbarous a Weed, or at leastwise as I love so 'batch grass') (Old Vanities), by a Volley of holy Shot thundered from Mount Helicon." He is chiefly known now on account of the obligations said to have been incurred by Mr. P., to his patronage, translation, that of the 'Divine Weeks and Works' of Du Bartas. (Bartas, Du, P. C.) There are two collected editions of Sylvester's works, both in folio, and commencing with the translation of Du Bartas. Their dates are 1633 and 1641. The second of them contains a supplement of posthumous poems; among which is that tasteless alteration of the 'Souls Errand,' which caused this fine poem to be erroneous of its author. SYMPHISOMETER (from symphisein, compression, and measure), is an instrument which was invented by Adie, of Edinburgh, in 1819, to serve as a barometer, for the pressure of the gas in the atmosphere, or of exhibiting the variations of its density near the earth. In account of its construction is contained in the first volume of the ' Edinburgh Journal of Science.' It consists of a glass tube B about eighteen inches long and seven-eighths of an inch in diameter, which is bored internally: at the upper extremity is a cylindrical vessel A half an inch in diameter, internally and two or three inches long; and the lower part of the tube contains, as in the gasometer, the instrument is quite filled with a vessel C of an oval form horizontally. The vessel A and the upper part of the tube B are filled with an elastic gas, either oxygen, the extremity b of the tube contains, another vessel C of an oval form horizontally. The vessel A and the upper part of the tube B are filled with a vessel C of an oval form horizontally. The vessel A and the upper part of the tube B are filled with an elastic gas, either oxygen, air, or hydrogen; and the lower part of the tube contains, which is the instrument being now brought to a vertical position, on removing the glass tube B, the gas in it will be compressed, and the pressure will rise. The instrument being afterwards returned to its former position, the vessel A will expand, and the gas in it will be expanded, and the pressure will fall. The instrument being again put in a vertical position, a counterbalance to the weight of the column of gas in B and to the expansive force of the compressed gas which is in the upper part of the tube and in the vessel A.

In order to form a scale for the symphismometer, the instrument, together with a good barometer and a thermometer, must be placed in a glass receiver in which, by proper syringes, the air may be rarefied or condensed at pleasure: then, on bringing the instrument to such a state as a thermometer with respect to density, that the top of the column of mercury in the barometer may stand at 27, 28, 29 and 30 inches, and marking the points on the tube or frame of the symphismometer which correspond to these, it will be seen that the distance between every two of these points being divided into one hundred equal parts, the scale p of the instrument is constructed. The particular graduation at each inch is made by the barometer, which stands at that point of the gasometer in the instrument, the numbers of inches and hundredths of an inch at which the top of the column of mercury in a barometer would stand at the same time in the same place. But the volume of the hydrogen gas changes in consequence of variations in the temperature of the atmosphere; and therefore a correction, depending on the amount of the variation in the volume of gas for given increments of heat, should be applied to the thermometer on the scale of the symphismometer in order to obtain the true height of the mercurial column in a barometer.

But, to avoid the trouble of computing and applying this correction to the instrument, the scale p of the symphismometer is made to slide on one side of a scale r which is graduated like that of a thermometer, by communicating different degrees of heat to the vessel A while the pressure of the atmosphere on the upper surface of the oil C remains the same, so that the gas in that corresponds to 294 inches on the scale of a barometer, and observing the points at which the top of the column in B is in these positions on the scale r are numbered so as to express, in degrees, the temperature at which the gas, which is being moved till its index (at 294 inches) coincides with the degree of the scale r corresponding to the temperature of the atmosphere, expressed by the degree of a thermometer r attached to the instrument, that the graduation on p corre.

Spending the top of the column of oil in $B$ expresses the height of a column of mercury in a barometer.

Dr. Robert Gordon, the writer of the article Meteorology in the 'Edinburgh Encyclopaedia,' having made a series of obser-
vations for the purpose of comparing the indications of the
symptomsphere with those of a barometer, found that the
former stood higher than the latter by quantities varying be-
 tween 0.08 inch and 0.017 inch, the temperature varying be-
tween 60° F. and 62° F. (Paragraph 4.) He found the same time
that, in general, the difference between the indications of the
two instruments increased as the temperature and pressure
diminished. The excess of the indications given by one in-
strument over those given by the other may be conceived to
have arisen from some inaccuracy in the construction of the
symptomsphere; but the variation of the excess is not so easily
accounted for; it may, however, be supposed to be caused in
part by the expansion of the gas not being exactly propor-
tional to the increments of heat, a circumstance which is
assumed in the subdivisions of the scale $r$, between each of
the complete inches, being made equal to one another, and in
part from some absorption between the oil and the gas.

It is inferred, therefore, that the indications of the symptoms-
phere cannot always be relied on as accurate measures of the
density of the atmosphere; but, since it has been observed that
it is frequently made in changes in that density, which are too small to be perceived on the scale of a
barometer; and since it is well known to be less deranged than the latter instrument by the motion of a ship at sea, it
follows that, in these respects, it possesses great advantages as a
marine barometer in indicating the approach of gales of
wind.

SYMPLOCARPS, a genus of plants belonging to the natural
order Arecese. It has instructive spathes, a short
spathix covered with tetrandra dioecies. The ovaries are
one-celled, with one ovule in each and a minute stigma.
The berries are consolidated, the seeds without albumen.

St. fadthc, Skunkweed or Skunk-kabbage, has a large aphyte
with numerous crowded fleshy fibres. The spathes are pro-
cocious, ovate, turbid, various in width, spotted, and sometimes
covered with dull brownish purple. The spadix is oval, on a
short peduncle covered with perfect tetrandra flowers, and of
the same colour as the spathes. It has wedge-shaped
sepals, truncate at the top, and edges inflated; the stamens are
opposite the sepals with subulate filaments equal in length to
the calyx. When the spathes decay, the spadix continues to grow,
and every part of the plant, except the spadix, decays. Within
the spadix at the base of each style is a round fleshy seed as large
as a pea, white, tinged with green and purple, and invested with
a separate membranous coat, and with a prominent embryo situated in a depression at the top. The leaves spring up some time after the flowers; they are numerous, large,
crowded, oblong, heart-shaped, and on long channelled
petioles. The plant emits an offensive odour; its tubers are
acid, but when dried and powdered, are aromatic.

It is considered an excellent remedy in asthma, catarrh, and
chronic coughs, and has also been employed in dropy, rheuo-
matism, and epilepsy.

(‘Linley, Flora Mexicana.’)

SYNABATHOCRINUS, a genus of fossil Conioidea from
the mountain limestone of Holland forest. (Phillips.)

SYNOCHUS and SYNOCHA, forms of fever recog-
nised by most of the older and more recent writers on
the practice of medicine. Sauvages described Synochus to be a fever
which lasted more than a fortnight without materially weakening
the pulse; while Cullen used this term to express a fever
which combined the two forms of inflammatory and putrid
fever, that is, a fever which at its commencement was inflam-
matory and at its close putrid. The inflammatory form of
fever which was characterised by running its course rapidly,
and marked by high excitement of the heart and arteries, was
called Synocha by Cullen. A putrid and low form of fever was
called Typhus. The latter term is now however applied to
all continued contagious fevers, and the former terms are not
often used at all.

TABLE. Since the article Table, P. C., appeared (in 1842) we have kept an eye upon it, with a view to its correction and amplification in this supplement. We were obliged to take much of our material from the description of other writers a long time. We have seen a majority of the books we cited. We have since seen many more, and have found several errors in our sources of information; but not more than, in the general laxity of bibliographical description, we were prepared to expect. We shall take the subjects in the same order as in the article above referred to; and when a table is merely mentioned by the author's name in the present article, it will be found in the former one with fuller description.

The restoration of the old numerical type, namely, that in which all the figures except 0, 1, 2, have a head or a tail, and in which the thickness does not vary sensibly from one part to another, was adopted and recommended by the Astronomische Society at the end of 1842; but it had previously been used by Mr. Baily in his detail of the Cavendish experiment, which forms one volume of the Memoirs of that Society. The writer of this article, who first suggested the revival of the old figure (and caused it to be employed in Taylor and Walton's five-figure logarithms, in their reprint of Barlow's tables, and in Hermann's Werk-Arithmetick, before any one else had used it) is decidedly of opinion that the change is yet wanting, the substitution of dull and rather dark paper for the bright and shining material now in general use, which dazzles the eye too much. Tables should not be hot-pressed, and not even pressed at all. The mischiefs of pressure are two-fold; first, the smooth surface thereby created makes the paper a kind of mirror, which has a bright image in one place, whereas rough paper dissipates the light equally in all directions. Second, pressure will cause the figures more much after pressure than before. It is also a mistake to suppose that great blackness in the ink, combined with great whiteness in the paper, is favourable to the reader. Every increase of the contrast, even and above what is necessary to perfect legibility, is injurious to it: jet upon snow would in time destroy the strongest eyes. Of all the things which are meant to be read, a black monumental inscription on white marble in a bright light is about the most difficult: one would suppose, to look at our specimens of expensive printing, that such an inscription was the model which it was intended to imitate, and if possible to surpass. We are satisfied, after many trials, to report, that a dull paper, of a whitish brown character, too thick to be seen through, and an ink which is of a dull-brown black, as it were the very deepest shade of the colour of the paper itself, are the things which render the things most eyes. Those who try it should remember that the first page read is not so good a test as the hundredth.

One of the most legible books we know of is the trade edition of Gibbon's Decline and Fall, &c., in twelve volumes octavo, London, 1820. It is considered by the booksellers themselves to be very badly executed. But printers and publishers are too much in the habit of forgetting that a book is a book and not a line engraving. They look at the page as a whole, and if the individual lines stand out and make their separate existences too perceptible, they pronounce it ugly. Accordingly, the uglier they hold it to be the more legible the reader will pronounce it.

We regret to see that, just as we are beginning to abandon the use of the thick even-sized figures, the Germans are taking strongly to them. Most of the modern German tables have therefore illegible heads of columns and rows. The heads of the tables of multiplication, &c., 1, 2, 10, 100, 1000, 10000, &c., are perfectly illegible: they are entirely different from those in the old edition. The numerals are of the same form and size as in Plummer, but the headings and lines are different. We suspect that some writer of more recent research on the quarrers of authors, of some hunter of old injunction cases, might find something about the history of these two books.

Cader's Table, Paris, 1797, goes to 10,000 X 100; and the printed 1000 X 100 in our article.

Breitenacker, Producten-Tafel, Hamburg and Gotta, 1841, goes up to 100,000 X 100.

There is a compression of this kind: in finding, for example, the multiplication of 62878, the number in the line headed 2800, and there, in one part of the page, opposite (6) 286, he finds the first three figures, and in another part, opposite to 78, the last three figures. The first part begins at 62878, and the other parts in which the following numbers are less than 60, and once for those in which they are above it; and an asterisk in the last part of the table occurs when it is necessary to add a unit to the preceding figures. This arrangement brings the table into ninety-nine pages octavo, and is very ingenious: but there is more risk of error in using it than we like. Again, multiplying five figures by one is not so difficult an operation that it need be avoided by using a table which requires attention at three distinct things. Lambert's table (1770), presently mentioned, contains the nine multiples of sin x for every degree, to six figures; and multiples of primes to those of 515.

The Munch table, mentioned in our last article, is 1610, J. G. Herwart, Tabulae Arithmeticae Prostrefaherametique Universales, a folio containing all products up to a thousand thousand.

In the Royal Society's Library is a table by J. C. Jentner-wen, Neu-erfundene Multiplikationen und quadrat-Tafeln, Berlin, 1825. The earliest table we have seen mentioned (by Lipensia) is — Thomas Finck, Tabula Multiplicaciones et Divisionis, Coen, 1565 (in this form). There is also, by the same author, Tabulae quotidianum usum accommodatae, Copenhagen, 1615, 16mo.

As Finck is an author of some interest in the history of tables (as will presently appear), we have some inquiry about these works, and we find that they are not in the library at Copenhagen; but that Muller's Cambria Litterata, vol. ii. p. 254 gives them as follows. It seems they were not intended for scientific purposes.

' Tabula Multiplications et Divisionis, seuematam Monetan Danice accommodatae, Hafnia, 1604; fol. ohb. ' ' Tabelliner, indrettet til daglig foroenen Regning,' Copenhagen, 1615, 8vo.

Under this head we ought to mention John Bernoulli (the younger), Sexcentenary Table, London, 1779, and Michael Taylor's Sexagenary Table, London, 1780, intended to assist the beginner in the use of logarithmic calculations. The former having 10° for the first term, and the latter 1°. Both were published by the Admiralty.

§ 2. Tables of division and of prime numbers. —Cherruc's table gives not merely the lowest divisor as stated, but every divisor, for all the numbers under 102000 which are not divisible by 2, 3, or 5. It is accordingly a larger (and we think a more useful) work than that of Borkhardt.

Branker's translation of Rhoenis, mentioned in our preceding article, is of London, 1668, much altered and augmented by D. P.: this D. P. is Dr. Pell. The table of primes, &c., to 100000 is computed under Pell's advice and direction. But there is preserved in several places the title of a work of Pell which we have never seen, and which we take from Lipensia: Tabula decem millium difficilium Numerorum, sive nempe omnem quin ad 0 ad centum Milliones [milli or logistic logarithms, the numerator being 10^10 for the first term, and 101° for the latter]. Both were published by the Admiralty.
second volume of Harris's 'Lexicon Technicum,' London, 1710.

Murdoch mentions the first part of a table (by A. Felkel) of the squares of odd numbers, all of which are given by 2, 3, 5, 6, from 1 to a hundred million, Vienna, 1776. We presume if this work had got as far as either Burkhart or Chenua, we should have heard of it.

II. To 3 squares, cubes, square roots, cube roots, and powers in general.—Perhaps the oldest printed table of squares is that in p. 30 of Pacioli's Summa, &c. [VITCA, P. C., p. 818; printed in 1494 and again in 1525, which however goes but to 9,000.] Henckius, Arithmetica, has an one which is claimed to be perfect. Augsburg, 1609, begins with squares and cubes of all numbers up to 360. Heilbronner (p. 627) mentions a tabula Ciboriana which gives squares up to 1000. Detached tables of powers are given in John Harold's Logarithmic, of which the seventh edition bears London, 1745, has all the powers of 2, up to the 144th, for the purpose of solving questions about chessboards and hornbowels. We have also the title G. C. Palmers, Arithmetrica, Erfurt, 1827.

Masers, at the end of the tracts on Combinations, London, 1795, has reprinted Hutton's square roots of (1)100 to ten decimals, and reciprocals to seven. We believe that Hutton first gave this table, which is printed in a separate leaflet, 4 vols. London, 1775, 1780, 1785. In Jonas Moore's Arithmetic, 1580, there are the squares and cubes of all numbers up to 1000, the fourth powers up to 800, and the fifth and sixth up to 200. These were reprinted in the edition of 1600.

Rogg mentions 'Art gastos nen-enterdekte,' &c. Dossau, 1755, 8vo., containing the cubes of all numbers up to 100,000, or at least professing to in the title-page to give the cube root of every number under a thousand millions of millions: perhaps the cubes went to that of 10,000, with a rule for the fifth figure. And here we may mention that we have seen almost the same thing, stating, not the extent of the table, as it ought to do, but the extent to which operations of interpolation will be effective.

§4. Pure Decimal Operations.—An anonymous work, 'The art of long and the eleavy,' Augsburg, 1526, gives every fraction less than unity whose denominator does not exceed three figures, nor its numerator two, to seven places of decimals. This is a useful table. We may also mention (not as having seen it) W. F. Wucherer, 'Beyträge zum allgemeinen Gebrauch der Dezimalbrüche,' &c. Karlsruhe, 1755, 8vo.

The oldest table we have found printed in English is in "This book sheweth the measure of numans or any figure of maner of hand, as well of woodde, as of lande in the field, and comtynge the true number of acres of the same. Newly invented and compiled by Sir Rycharde Benoyn Chancel of Moray, in London. Printer to the late Thomas his hospital by me James Nicolson.' There is no date, but Nicolson's dated works run from 1536 to 1538. There is another edition (which omits the table) printed by Thomas Roycroft, 1539, but we have not seen it. There are double-entry tables of the rudest character, for finding the number of acres in a given length and breadth, and for casting up payment at per perch, per acre, &c.

As a matter of Table I. The following is a bibliographical history of the early part of this subject is so incorrectly given, as well as ambiguously, even by the best authorities, that it will be worth while to collect the several heads, distinguishing what we are obliged to take from other sources, by putting the name of an authority (of which we have usually two or three) to the latter. Much confusion has arisen from the double meaning of the word 'publication' in the century following the invention of printing, when it was applied equally to the issue of a printed book and of a manuscript. We are only concerned with the former; and it is sometimes difficult to distinguish between the two.

That ALBATORIUS [P. C. S.] had substantiated sines for Ptolomæus's chords,—that he had also used versed sines and tangents, and of the tables of their arcs which he compiled and issued (in manuscript at least) tables of sines to two or three decimal places, 60,000, 10,000, and 10,000,000, are historical facts of notoriety. Our question is, what tables were first printed? On the book which Regiomontanus actually printed, out of his long lists of those which he published and intended to publish (as set forth in his own 'Index Operum, &c.' printed at Nürnberg by himself, his heirs, Doppelmayer, Do Cunph et Murr, Vienne, 1560), there are either not words, or at variance. In the vague manner in which books and their contents are frequently described by professedly mathematical writers, a good resource is often found in the catalogues of general bibliographers.

The 'Tabulae Directionum Profectionumque' of Regiomontanus were published by himself at Nürnberg (without date, probably about 1475), and were reprinted at Venice in 1485. But we cannot ascertain that either of these contained tables of sines. But Hall (Repart. Bibilogr.), who gives their titles, gives that of the next edition (Augsburg, Ehr. Randolf, 1490, 4to.) in a fuller manner: from which it appears that there is appended to it a table of cosines and tangents, in minutes, in which Regiomontanus states that Regiomontanus had not given such a table in the former edition: they are, 'Tabella Sinna recti: per gradus et singula minuta divis.' Ad Tabulae Directionum Mag. Joh. de Regiopontano redactae, Augsburg, 1503, 4to. But from the description it appears that this table does not belong to the work, since it follows even the printer's insignia. And Hall also met with it as a separate work; being, as appears from his description of the lines, pages, &c., absolutely the same as that which was appended to the Tabulae Profectionum. Accordingly, until something earlier or more definite is produced, we must say that the first known printed table of sines is an anonymous table, to minutes, in 4to., printed at Venice or Bologna, 1558, 12mo., and we suspect that these tables were to a radius of 600,000, as in that edition, which is of Venice, 1504, 4to. In it we find a minute-table of sines, headed 'Incept tabella sinum recti,' and with a column containing differences for multiplying.

Delambre and others mention Regiomontanus as having given the first tables of sines in this work under the name of tabula facunda. It is in the edition of 1546, and was reprinted by C. P. C., in the 'Institutiones Geographica,' Antwerp, 1545. It is to degrees only, and to a radius 100,000, and is a table of cotangents, not of tangents. Delambre mentions an edition of the work, edited by Gau- seius, in 1558, which contains the tables printed, in 4to, of the radius 100,000, and gives the minute-tables of cotangents, not of tangents. We have seen a copy of the tables of sines and tangents, of this we can find nothing. As yet we have no sines calculated to the new ordinary radius of 10,000 &c. Of these the earliest that we have seen (and we find no earlier ones mentioned) are those of Peter Apian in the 'Institutiones Geographica,' &c. Ingolstadt, 1533, 4to. They are minute-tables to a radius of 100,000, and were reprinted the next year in the same author's 'Instrumentum primi Mobilia,' Nürnberg, 1534, 4to. Apian states that they are of his own calculation, and this is to us a strong presumption that no such tables had been previously printed; for Apian was a great reprinter of the writings of others at his own press, and very unlikely to have recalculated by his own table which he knew to exist already. The statement that the work of Regiomontanus on triangles (Nürnberg, 1533, folio) contains tables of sines, is incorrect: we know it from examination of two perfect copies. As we are now contradicting our own previous assertion [Tabulas, P. C.,] we will point out how we were misled. Lalande (Bull. Astron.) says that the first edition of the work, Basle, 1538, has in the title-page 'una cum tabula sinesis.' Now the content of the title-page is that Apian had only printed 'un tabula sinesis' (Basle, no date, known to be of 1561), which does contain tables of sines, took the liberty of presuming that the first edition was the same in contents, title, and place; in all of which he was most certainly mistaken. In 1642, Rheticus, the most laborious of all the table computers, made his first appearance as the editor of a work of Copernicus: 'De Laticibus et Angulis Triangulorum,' &c., Wittenberg, 4to. (Weigler and Kastner.) This contains a
minute-table of sines to a radius of ten millions, being the first-published seven-figure table. The table which appeared in the first such publication, the work of Copernicus (Copernici Commentariolus, P. C.), is an abridgment of the manuscript, going only to every ten minutes, and to a radius of 100,000.

In 1541 appeared one of the tables which have obtained most fame. This was Adriaan van Roomen's, and these tables contain propositions Potensic de Sinibus et Chordis, in tabula composita Tabulorum Sinuum per Joan. de Regiomontano. Adjectae sunt Tabulae Sinuum duplissimae per eundem Regiomontanum, Nuremberg, 1541, folio (Kastner, 111). The two tables of sines are both minute-tables, with radii of 6 millions and of 10 millions. The table of tangents to every degree is repeated again under the name of tabula facunda.

In 1548, in pursing the route of analogy, which suggested to him the formation of a table giving all the ratios which exist between the sides of a right-angled triangle; by which he was led to the invention of what were afterwards called sines, and of the modern sines, that he has the perpendicular and the base to a hypotenuse of ten millions; in that of the tangent and secant he has the perpendicular and hypotenuse as a base of ten millions; in that of the cotangent and cosecant, he has the base and hypotenuse to a perpendicular of ten millions. The same description is adopted in his larger work, of which we shall presently speak.

In 1548 Erasmus Reinhold (who had been the colleague of Rheticus in teaching mathematics at Wittensberg) published the 'Liber Tabulorum Directionum,' Tbingen, 4to. In this work, for the first time, occurs a canon facunda (not yet a table of tangents) carried to every minute. Both sines and tangents are given accurate to 104 places in the minutes.

This work of Reinhold, though founded upon Regiomontanus, must not be confounded with his professor's edition of the 'Tabulae Directionium' of Regiomontanus himself, which had tangents only to the first degree of the quadrant and which the last edition being in 1606. (We have not thought it worth while to catalogue reprints.)

In 1552 (Delambre) Maurolycus published his edition of Theodosius, Menelaus, etc. (Meuseni, 4to.), containing the three tables, that of sines, the tabula facunda, and the tabula beneficia (as he called the present table of secants). This table goes only to degrees (except that tangents and secants are given for 15, 30, 45, 60, and 69 minutes of the last degree of the quadrant) and is to a radius of 100,000. Delambre, etc. suppose that these are the first tables of secants which were published, and they accordingly attribute the invention to Maurolycus. But we have seen that it is due to Rheticus and Finck (presently mentioned), who lived close to these times, states expressly that Maurolycus borrowed this table from Rheticus.

In 1562 a pupil of Rheticus published a table of sines to every minute, and to a radius of ten millions. This was Samuel Eisenmenger (or Siderecrassus, as he wrote himself), in his 'Libellus Geographicus,' Tbingen, 4to. And there

Reinhold taught too higher branches, and Rheticus the lower.

It is very difficult to state whether the advantage (or its absence) after-mentioned (and afterwards named) caused the writings of Rheticus to fall, that Weidler, himself a brilliant worker in the field of writing and printing of His- tory of Astronomy, there giving minutely the dates of Rheticus's degrees from the second to the third minute, and set the table as in the time when he and Reinholt were colleagues; it had always been customary to have two teachers of mathematics—i.e. Hil- ler and Maurolycus as the works of Rheticus, and in particular having nothing of the publication of 1561, of which we may therefore be pretty sure there was not a copy in the library.

It was, as we find stated in various quarters, a table of sines in the work on dialling of Hermann Wittenfeld, 'Conformatio Horologiorum,' in which the first edition is said to be of Heidelberg, 1576, 4to.

The first complete canon to every minute (that of Rheticus in 1561 being to every ten minutes) was Vieta's 'Canon Mathematiorum, &c. de Triangulis, eundem Adscribendo,' Paris, 1579, folio. We have described this work in TAB, p. 516, and shall here only make a few additions. Besides the three title-pages there mentioned, there must have been a fourth; for in the title-page of that which Delambre examined the motto was et die quoque quiesce, which certainly belongs in either of the three seen by us. The work has well obeyed the direction given: it has lasted in silence, having never been re-embarked in catalogues or histories till modern times. Copies seem to have been rare in Germany; neither Weidler, Heiblondon, nor Kastner mentions it. Hutten never saw but his own copy. Montucla (in France!) never saw more than one in the royal library, and one sold at the Sou- bise sale (but it is not in the catalogue of that sale), which the historian would fain have bought, had not a curious bid too high. And this was only by the time Montucla's second edition was written, for by the mention of it made in the first edition it is clear that the master had never seen it. We have ex- amined in London at least eight copies. We have mentioned [VIETA, P. C.] the complaints which the author had to make against the print, and Montucla states that he bought in as many as he could. There were several details which were having taken place in the printing: and the following is worth mention:—To one of the copies we have seen (as well as to one of those of the 'lecture' edition) is appended a sheet, in correction of a case of error in the sheet of the collection of formulæ: this is a separate publication, with the date (1579) and printer's name on it.

Vieta imitates Rheticus in his method of writing the tables, but in addition uses the sine axis and calls the table of tangents facunda, and that of secants facundissima. He complains that elegant names have not been found, and states that he gets his denominations from certain Raphaeli (as he calls them); it is not the name that has been the cause of the modern table. He has published, in a later work, the Responsa, etc. [VIETA, P. C., p. 516], published in 1568, he names and objects to the words tangent and secant, which by that time he had seen. And he proposes to call the tangents proponit et aminea, and the secants transmutans lines.

As to the matter of Vieta's tables, it is worth notice that they must have been made by independent calculation. They do not exhibit the errors in the last tangents and secants which appear in all writings prior to the more correct publication of Rheticus by Pitiscus. On the additions made by Vieta to the theory of trigonometry, it is certain they do not affect it, though they may simply say that they made the computation of a trigono- metrical canon a much easier thing than it had therefore become. Delambre is quite right when he observes that the 'Tangenti et secanti canon' have no beneficial relation to the last which relates to the non-logarithmic part of it. Had he known a little more of Vieta, he could have reinforced his assertion. For the method of solving equations which he describes (evidently not understanding it) as an obscure mixture of division and extraction of roots, was the slightly amended form of Vieta's numerical exxogis, to which we have referred in EVOLUTION AND EVOLUTION, P. C. S., p. 104. And as, by Cellibrand's account, we trace the com- mencement of Briggs's labours shortly after the time when Vieta first published this exxogis, it is by no means an un- likely conclusion that his labor of extraction and comparison given by this mode of solving equations, first put it into his head to construct the table.

Purbach and Regiomontanus had seen the advantages of adopting decimal notation, and their 'Durchgang,' and the radius, 4to. etc. was a remnant of sexagesimalism. It was reserved for Maurice Breslau to show himself a century behind his time, by publishing in his 'Metrices Astronomicse Libri Quatuor,' Paris, 1581, folio, seven tables, that of tangents, and secants, or as he calls them, sines, adscriptae, and hypotenusae. Thus, the radius being 60°, the sine of 5° 20' is given as 50° 30' 34'; and the adscript and hy- potenusae as 1 cos 35° 46' 56". Acuttedomus as we are to look upon sex- agesimal division as sacred to angular and lunar measure, we are apt to forget that the time was when such subdivisions were rarely used in Europe.
As yet do not find the modern names of tangent and secant. These were introduced in 1589 by a young man of the name of François Viète in De aequationibus... His work is well known, his in his 'Geometria Rotundi Liber XIV.' Basle, 1640. His part in the matter was quite forgotten, and has been recently revived (see Philos. Trans., May, 1645). He introduces the name of tangent, which he properly enough, as well as the names of cotangent, secant, and cosecant. He observes that these terms are foreign to him, but new and useful, and not without some reason. It is said to be sometimes of note in some calculations which are supposed to be the collection of the editor. Besides, Snell, the respected editor, was only seventeen years old when the work was published.

The tables of sines, tangents, and secants, which were introduced in his work, were afterwards made in a radius of 10 millions. Finck deserves a much higher name than he has got; for the contents of this work alone: there are other writings of his, which we have not seen. He calculated his own secants by a theorem which answers to the formula

\[ \tan(\theta) = \tan(\frac{45\theta}{2}) \]

In 1556 Clavius published at Rome, in quarto, his edition of the Theodosius, to which is appended a treatise on triangles, and a table of sines, tangents, and secants, under those names. They were reprinted in the folio collection of his works, Mayence, 1611. It is clear, on inspection, that these tables are, as far as tangents and secants are concerned, a reprint of those of Finck, in their preliminary theorems, in their arrangement, in their omissions, and in their errors, as well as in the new terms with which they are headed. The names of the sines and tangents, as well as those of the secants and cosecants, were not used by him; but they were Protestants, and Clavius was a Jesuit, high in favour at Rome. Delambre expresses his astonishment that Clavius, in recapitulating the names of celebrated writers on dialling, should have omitted the name of Christian Rahn, as if the fact was, that the Munster followed Luther. We are not quite certain that a greater than Clavius was altogether exempt from this laughable weakness. When Vieta suppresses the names of his author's works, as those who copied them merely rhodiused, we may almost suspect that he wanted to avoid speaking of Rhetius and Reinhold; for he was very intolerant.

In 1591, Philip Lansberg published 'Triangulorum Geometria Nova.' Leyden, 1600. In 1592 Magini published 'De Planis Triangula Liber Unicus.' Venice, 4to. Both these are copied from Clavius: but Magini at least, who goes beyond Clavius in historical reference, wholly supersedes the name of Finck.

We at first thought ourselves unable to give a date to the tables of Stevinus, except within a few years, and conjecturally. That he published his Arithmetica in 1585, and that Snel* collected his works in Latin in 1605-8, are the facts which are supposed to mark out the known limits of his career. The tables must have been published after 1598, since Vieta's names for the tangent and secant do not appear in Snel's work; and after, for Vieta's own works were of very slow travel. We ourselves believe fully that the Cosmographia, which contains the tables, was never published until it appeared in what is called Stevinus' Opera, at Leyden, 1610. These tables refer to every minute, to a radius of 10 millions, and they are copies of Finck, Clavius, &c. We are informed that recent researches in Belgium have made it appear that Stevinus was born in 1548, and died in 1620, which puts our opinion beyond dispute. The mistake about Snell seems to have originated with Gerard Vosius.

In 1588, Nie Raymar, Unea Didiwmus, published 'Fundamentum Astronomiae, id est nova Doctis Sinum,'&c, Strasburg. We cannot make out from the descriptions, whether this work contains tables or not: probably it did.

The published the first English trigonometrical table is a point which we have never seen examined: and we must investigate it in the best way we can from rather scanty materials. We cannot find the word sine mentioned in the works of Recorde, nor in the English works of either Digges, father or son, nor in those of John Dee; nor indeed in any work written in English before Blundeville, except that of Burroughs presently cited. In the 'Ale, seu, Soluta Mathematica' of Thomas Digges, London, 1573, 4to., trigonometrical tables are given for which a reversion

---

* It can be made very obvious that Stevinus was alive throughout the whole of the printing of these two volumes (or five volumes bound in two). In the very Gates of London (where excepted), the author assumes himself not to be fitting any annotation amongst the Commendatore and not made up for the commen of the printer, and the printer could not wait. And thence it often happens that there is a very small proportion of the subjects which are supposed to be the collection of the editor. Besides, Snell, the re-
to a radius of 100,000. Peculiar to this table is a heading by which the sine, tangent, secant of the complement, or defect from 90°, are also made to belong to the excess above 90°; the tangents, secants, and secant of 90° are made to be those of 100°.

The history of the rest of the works of Rheticus was, till recently, very inaccurately told, and there is still some confusion about it. After Rheticus had published his two-minute canon, already noticed, in 1651, he was occupied till his death in 1676, in what is, beyond a doubt, the most laborious work of calculation that any one man ever undertook: a complete trigonometrical canon, composed of three trigonometric tables, namely: the tangent and secant; the tangent and cotangent of one degree, with a table of decimals, sine to every tenth second, and to fifteen decimals, with the first and last degree to every second, and tangents and secants to every minute, and to fifteen decimals. It is the thought, indeed, that this great work might have been introduced, if he had known what Vieta had done. At his death, he had finished this work, within a mere trifle: what little remained to do, was done by his pupil Valentinus Otho, and part of it was published at Neufeld in the Palatinate, 1696, in folio (sometimes bound in two volumes, from its thickness). The title of the book, which was published at the expense of the Emperor Maximilian, is "Opus Palatinum: but a translation of a Georgio Joachimo Rhetici, conceptum: L. Vechulli, Otho Principia Palatini Frederici IV. Electoris Mathematicum consument." The contents are (afterpreface) three books de Fabrica Canonii, on the construction of the canon; five books, in which Rheticus published three books on right-angled spherical triangles, and four books on right-angled spherical triangles, by the editor, Otho; three subsidiary astronomical tables called mathematicas, of nineteen places, giving the sines, tangents, tangents for every ten seconds, for a radius of 10,000 miles, or, as we should now say, to ten places of decimals; a list of errors, and, lastly, a good table of cotangents and cosecants for the first half of the quadrant, to every ten seconds as before, and to a radius of 10 millions. The appearance of the last table is merely the editor's want of judgment; it is clear that the publication of this plan was resolved on, and is much less accurate than the great table to ten places.

Within a short time after the Opus Palatinum was published, it was found that the tangent and secants towards the end of the quadrant became more and more erroneous, and at the extreme end very erroneous indeed. All persons who knew anything of trigonometry are aware that, to calculate the tangent or secant of an angle near to 90° true to any number of decimal places, requires that the cosine should be calculated to a greater number of places. Rheticus seems to have foreseen that the tangent and secant would become more and more erroneous near places than those which were published. When the defect was discovered, the advisers of the Elector Palatine, Frederick IV., to whom the work was dedicated by Otho, called a meeting of the scientists at Worms, and the manuscript of Bartholomew Piticus of Grünenberg, in Silisia, who had been his own teacher, and who was still in his service as chaplain: we suppose this means that Piticus himself, was the adviser. Piticus applied to Otho, then an old man, for the larger tables of sines which Rheticus had known to have calculated: Otho was never able to find them; but at his death they were found among his papers. Piticus accordingly made two publications; but so confused and ambiguous were the statements respecting them, that some of our readers may almost doubt the fact.

These two publications were as follows: 1.---He corrected all that part of the great table of the Opus Palatinum in which the tangents and secants were sensibly erroneous, being the first 86 pages. These he rebound, and his reprint to the 640—86, or 454 remaining pages of the great table. He then cut away all the Fabrica Canonii, the books on triangles, the Meteorographia, and the small table of cotangents, &c., and added to his own 86 pages and Otho's 454 a short description, or commentario, as he calls it. This of course gives a thin foot. But we collect from Delachaux, in his "Histoire des mathématiques," the following facts with respect to the "copy," that the 86 pages were such things as were completed copies of the Opus Palatinum, with the 86 correct pages substituted for the incorrect ones. And we presume that to these the separate title of the commentario was not appended, being printed off in the same sheet. 

Wieland, apiary of Motscho, given Heidelberg, 1844, and Landana resells them by taking Neustadie to be Latin for Heidelberg! The Neustadie here mentioned is now part of Bavaria, lat. 49° + long. 11° .

The rest of the French savans (to whom the subject was particularly interesting, on account of its connection with the Tabulae du Cadastre, then preparing) missed the date of the correction, which never appeared on the face of the book, or the commobserver. 

The person who is used to accurate descriptions of books might possibly, without this warning, throw away the thin folio we are speaking of, under the idea that it could not be the one he was looking for. The title-page of the thin folio, without date or, on the first page, as follows: "Georgio Joachimi Rhetici magnus canon doctrine triangulorum ad decadas secundorum scilicet, et ad partes l 0000 00000. Recens emendatis a Bartholomeo Piatico Silasie. . . Additiones brevissime commonefactio de fabrica et usu magni Canonis doctrine triangulorum Georgii Joachimi Rhetici. Neuwiedi Typis Nicola Schrammii MDCCXVIII." It thus appears that the date is 1697, which no one has yet noted, except Kastner, copying an older description, apparently without any distinct separate knowledge of what he was describing. 2.---On the 16th of May, 1606, in the index to the Fabrica, he introduced the following, under a long descriptive title beginning with Thesauras Mathematici.

"The ten-minute canon (1651) which we have described, and of which the memory was almost lost, introduced the secants, completed the system, and suggested to Vieta both the extension and its form. Had Rheticus published his own large table before his death, in 1676, it might have been otherwise: but deferred publication was calculated, to twenty places of the sines of every 10th, 20th, and 30th, and 50th second in the first 35 minutes to 22 places (this last table was done by Piticus himself). Piticus died in July, 1618, very short after the publication of the separate "copy.

When we come to reflect, we find that the tables of Rheticus did not make such an epoch in the history of these things as might have been expected. The ten-minute canon (1651) which we have described, and of which the memory was almost lost, introduced the secants, completed the system, and suggested to Vieta both the extension and its form. Had Rheticus published his own large table before his death, in 1676, it might have been otherwise: but deferred publication was calculated, to twenty places of the sines of every 10th, 20th, and 30th, and 50th second in the first 35 minutes to 22 places (this last table was done by Piticus himself). Piticus died in July, 1618, very short after the publication of the separate "copy."

The copies of the works, the Opus Palatinum, and the Thesauras, which belonged to Delenin, were bought at the sale of his books by Mr. de Bourgeois. The copies of the Thesauras were corrected by them for the use of the society, to be printed at the running titles of the columns. The uncorrected copy will have, as ought to have, Basioc Differentia Hypothomatem. But the corrected copy (quo curator) (quo curator?) will have, as ought to have, Basioc Differentia Hypothomatem. 

The copies of the works, the Opus Palatinum, and the Thesauras, which belonged to Delenin, were bought at the sale of his books by Mr. de Bourgeois. The copies of the Thesauras were corrected by them for the use of the society, to be printed at the running titles of the columns. The uncorrected copy will have, as ought to have, Basioc Differentia Hypothomatem. But the corrected copy (quo curator) (quo curator?) will have, as ought to have, Basioc Differentia Hypothomatem.
done. In the Berlin Memoirs for 1786, John Bernoulli (the younger) revived the knowledge of the *Opus Palatinum* and the *Thesaurus*; and several other men had previously come at some statement to the effect that Pitiscus had once received instructions to correct the former. But Bernoulli knew nothing of these corrections, and nothing was known until chance threw a copy of the *Opus Palatinum* into the hands of Prof. Prony, who described it in a paper printed in the fifth volume of the Memoirs of the Institute (1804). Delambre gave an accurate account at the beginning of the second volume of the *Histoire des Astronomes Modernes,* a work which had given nothing but mistakes. Hutton knew as much as Bernoulli.

Kastner (1796, who would have got much more credit if he had given a proper name to his work of bibliography, instead of calling it *Napierian Logarithms*,) has set down and given an account of all the matter, except the corrections of the *Opus Palatinum*, on which he could only quote from a periodical of 1789.

In 1696 Pitiscus published his own work on Trigonometry, with tables, generally to seven places, and having intervals which may be described in the notation of our former paper as $\frac{1}{10}$, $\frac{1}{100}$, $\frac{1}{1000}$, etc., of the 45th. The edition of 1688, now before us, has, of course the corrected tangents and secants. It was reprinted again in 1618, and Dechales mentions a reprint, by Henrion, in 1629.

Pitiscus will always be remarkable as the priest who wished that all his brethren were mathematicians, to make them masterful and benevolent.

Among the non-logarithmic tables, which were published after the invention of Napier turned all the calculators another way, we have mentioned in our former article Schooten's *Tables Astronomicae,* published in 1638. Leibniz's paper was reprinted in 1638 (7) and we know there is an edition of 1672 at Rouen, and of 1683 at Brussel. Editions are mentioned of 1640 and 1664, and also a Spanish edition, Brussel, 1688. John Mead's *Tables,* Strasburg, 1619, contain sines, tangents and secants, squares, and cubes. Those of Adrian Mictus, 1633, give a complete canon, to minutes, to seven decimals. In 1627 Snell published his *Doctrine triangulorum canonum,* Leyden, 1638, containing complete canon to seven places. Struige's *Synopsis Trigonometricum,* Danzig, 1616, gave a five-decimal canon, to minutes. Albert Girard's *Tables des sinus,* i.e., Haque, 1636, are to five decimals; there was a Dutch reprint in 1629. Adrian Romanus gave tables (Delambre, *Astr. Mod.*, vol. ii. p. 35) in 1609; they were taken from Clavius. The contents of this paragraph are taken from different sources, and not from the books themselves. We might mention some anonymous tables from various catalogues, but anonymous works of this kind are so rare that we always suspect them.

Aldred's *Encyclopedia* (1649), the earliest work which has been compared with modern works of the same name, gives nothing more than a canon to degrees and seven decimals, with another to ten minutes and five decimals. The name only of logarithms is mentioned, and an insufficient definition given of the latter.

§ 6. We shall now add something to our account of logarithmic tables, including a fuller description of a few of those mentioned in our former article. The date and name, when unaccompanied by a title, will serve as a reference to that article.

1614. Napier. It must be specially noted that the logarithms which Napier himself published are not precisely those which are now called Napierian; that is, they are not the simple logarithms to the base $e = 2.7182818...$ As the sines increase, his logarithms decrease. As he uses no decimal point, both his sines and logarithms are integers, the former to a radius of 100,000. And if $N$ be a sine and $L$ the logarithm of it, as they stand in Napier, the equation connecting them is

$$L = \log_{10} N - 10,000,000 \times 10^{10,000,000}$$

Delambre proposes to call them *Napierian* logarithms, and to restrict the term *hyperbolic* to the modern Napierian or $e$ logarithms.

1618. Benjamin Urania. The *Magnus Canon,* besides

[...]

In his preface he says, *Mammatomo astroem, bone Deus, quantum et quocumque syno theou ologassmnto. Ex quarto panditam est hoc secundo, utinam Theologiae non incommunientur, hos auere, quos saepe aere, quos semper et seorsum.* Perhaps the union of the characters of divine and mathematician gives a prouder right to speak well of the latter; for Barrow says, *Theorometriae caelestium, tali erat animus, aut anima, quae diu est, patiens genere hominum est mathematici.* We accept the el saecurum, for there is no saying how the moderns might translate the first epithet.
by Montucula, and the history of the book is as follows:

Kepler had stated that Byrgge had invented the very same logarithms as Napier many years before the latter published and got them published by Wittenburg. Without going into the work on perspective (Casell, 1630), says that his brother-in-law and teacher, Justus Byrgius, had, twenty years before that time, made a table of progressions with differences of 10, 100, 1000, which have also been kept by the author of the text at Prague in 1620. This announcement contained no notice, until Kistiner informed Montucula how he had come across some old tables which he had bought, and which had lain by neglect. And in these old tables, he says he found the work of Byrgius. This occurs in the second edition of Montucula's History, vol. ii. p. 10; see also Kistiner's History, vol. ii. p. 375, and vol. iii. p. 14; and Delambre, Hist. de l'Abs. Mod., vol. i. pp. 660-666. It will be noticed that Byrgius did not publish till six years after Napier; so that in all probability Napier is first in point of invention as well as publication. His system begins with the logarithms and 10 as a number; for every increase of the logarithm by 10, the product is multiplied by 10000, so that 10n has for its number 10000 (10000)−n. This is undoubtedly a rude table of logarithms, or rather of numbers to logarithms: and since Byrgius carried it up to 200,000, the number 10n for each number, to make real the radius ten millions. There are five columns, of which this is a specimen:

<table>
<thead>
<tr>
<th>40° 40' 26&quot;</th>
<th>16° 10' 00&quot;</th>
<th>49° 50' 59&quot;</th>
<th>355.3474</th>
<th>42° 4' 4&quot;</th>
</tr>
</thead>
</table>
| This table has 701, and the sine being 7010000, the angle is 40° 40' 26". The logarithm is 355.3474. And if 1000 represents 24°, then 701 represents 49° 50' 59": while if 1000 represents 60°, 701 represents 42° 4' 4". We were wrong in saying that it was this set of logarithms that was republished in 1700, as will presently appear.

1624. John Kepler, *Chilias Logarithmorum*, Marburg, and 1625, *Supplementum ... continens Pseudepota de curum Uniformium Proportionum e Theodoro Dillingenius*. See a very full account of them also in the first volume of Delambre's History of Modern Astronomy. The logarithms are strictly Napierian, 0(1)10000, but for these entries are put to the number on each number, to make the radius ten millions. There are five columns, of which this is a specimen:

<table>
<thead>
<tr>
<th>40° 40' 26&quot;</th>
<th>16° 10' 00&quot;</th>
<th>49° 50' 59&quot;</th>
<th>355.3474</th>
<th>42° 4' 4&quot;</th>
</tr>
</thead>
</table>
| This table has 701, and the sine being 7010000, the angle is 40° 40' 26". The logarithm is 355.3474. And if 1000 represents 24°, then 701 represents 49° 50' 59": while if 1000 represents 60°, 701 represents 42° 4' 4". We were wrong in saying that it was this set of logarithms that was republished in 1700, as will presently appear.

1626. Wingate, *Arithmetische Logarithmique*. Under this head, in our last article, we mentioned the difficulty about the date of the book by which Wingate introduced Briggs's logarithms into France. We have since found a copy dated 1625, and we are satisfied, from the date of the *privilege* and other things, that this was the first edition. That date appears on the subject, and on all the other edition, to be April 14, 1625. The first edition is from the same types, except in their title-pages, and a page or two of the parallel explanations. The latter has also an addition to this subject, as would have been expected, and has also additional (perhaps, for the same thing may have been torn out of our copy of 1625) a folding sheet of mean proportionals between 10 and 1. The contents are,—seven decimal logarithms of numbers 0(1)10000 with interpolation differences, and 0(1)45° logarithms of sines and tangents. This is the introduction of Briggs's logarithms into France; that of Napier's was made, as noted, by B. Vincent: but the dates should have been 1619 for the *Descrip.,* and 1620 for the *Constructo.*

1626. Hinorin. In our former article we left this work in doubt. Now we learn that Hendron wrote on the propositional comparisons in 1626 (reprinted in 1681) and on the rule of proportion (which we take to be Gunter's scale) in 1626; and that this last work consists of seven pages, and is rather a singular manner. It will be seen that we have (p. 498) noted Sherwin as stating that he examined his table by one of Vlacq's, in large octavo, printed at Gouda in 1626, of which a copy we find in the Bodleian. There is no table in the edition of 1626, and the table we find corresponds in every respect, except that there is no author's name: but no one except Vlacq can be mentioned, who was in the least likely to have printed logarithms at Gouda in or about 1626. And there we have no doubt is the real first

1853. J. B. Morin, 'Trigonometria Canonice Libri Tre,' Paris. Seven-decimal Logarithms; of Numbers 0 (1) 1000, with tables of Sines and Tangents 0 (1) 45°. R.
1864. Cruger, & yielding tan, as to Tables called, twenty-seven

Those every first tangents, algorithms natural

80° of Vlacq

1651. 1685. 1706. 

J. Deparcieux, "Harmonie Coelestes," London. The logarhythms have separate table-pages, and might, if torn out, pass for separate works. They have the decimal point and are to six decimal places. Sines and tangents 0 (1) 45° 45', 45' 45' 45', etc., 0 (1) 1000, without characters. Wing was a much more learned man than his reputation (which is that of an alman-cook) would imply.

1668. John Newton, 'The Scale of Interest, or the use of Decimally,' has a table of logarithms to ten decimals 0 (1) 10000 arranged in lines of decades, with a separate table of proportional parts.

1681. Vlacq, 'Tabulae Sinuum,' &c., Amsterdam: also 1693. Vlacq, 'Table de Sinus,' &c., Amsterdam; and 1681. Vlacq, 'Table de Sinus,' &c., Amsterdam, a great many small tables of logarithms bear the name of Adrian Vlacq. Those before us, which have the same introduction, one in Latin, the other in French, the third in German, have sine tangents, secants, and logarithms of sines and tangents, to every minute and to seven decimals. Also, seven-decimal logarithms from 1 to 10,000, headed H. Bricigg Tabula Logarithmicae. The same table and a second one are in 1706. Oeum, 'Tables des Sinus,' &c., Paris. This is really Vlacq in every particular as to the tables, though his name is not mentioned.

1695. Cursus et Mundi Mathematica, the first volume has seven-decimal tables; logarithms of numbers of 0 (1) 1000; of sines and tangents of 0 (1) 45', and the sines and tangents of 0 (1) 45'.

1704. Wm. Leybourn, 'Cursus Mathematicum.' This book has internal evidence of having been written before 1660. Seven-decimal logarithms of numbers 0 (1) 10000; six-figure logistic logarithms 0 (1) 8', and 1 (1) 12'; sines, tangents, and secants, 0 (1) 45'; the names cosine and secant not used.

1695. John Wing (nephew of Vincent), 'A compleat Body of Trigonometry,' formerly published by Vincent Wing, London. Five-decimal logarithms of sines and tangents, 0 (1) 1000; of numbers, 0 (1) 10000. 1704. J. H. [arris], Table of Logarithms, quarto, mentioned in Hutton's sale catalogue.

1705. (Second edition.) Anonymous, 'A Table of Logarithms for Numbers increasing in their natural order, &c., London. Six-decimal logarithms of numbers 0 (1) 10000. The last printed part has a separate title, 1704, 'A Triangular Canon Logarithpic,' London. Six-decimal logarithms of sine, tangent, and secant 0 (1) 45'. As far as appears, this table was got up by J. Seller and C. Price, mathematicians in the King's service, who have not scrupled to sell their own table of logarithms as well as their own quadrants.

1710. John Harris, 'Lexicon Technicum,' vol. ii. This volume contains seven-decimal tables of logarithms 0 (1) 10000, and a complete canon (including versed sines), 0 (1) 45', both natural and logistic. There is also a table of proportional parts for every integer from 44 to 4300. These tables, except the last, seem to have been published by Burnet.

1721. In this year was printed at Pekin, by command of the Emperor Kang-Hi, in Chinese type and in three folio volumes, Vlacq's logarithmic tables of sines, &c., to ten seconds, and of numbers to 100,000. (Brunet, from Vega, who had seen it in Vienna.)

1741. Depariieux, 'Noueaux Traite de Trigonometrie Rectiligne et Sphrique,' Paris. Depariieux is so much better known by this work that all the following authors are neglected. The tables are all to seven decimals (though the decimal point is not used). There are logarithms of numbers 0 (1) 20000; sines, tangents, and secants, &c., 0 (1) 45' 45' 45', and logistic of the trigonometrical parts has a separate title, 1741, 'A Triangular Canon Logarithmic,' London. Six-decimal logarithms of sine, tangent, and secant 0 (1) 45'. As far as appears, this table was got up by J. Seller and C. Price, mathematicians in the King's service, who have not scrupled to sell their own table of logarithms as well as their own quadrants.

1710. John Harris, 'Lexicon Technicum,' vol. ii. This volume contains seven-decimal tables of logarithms 0 (1) 10000, and a complete canon (including versed sines), 0 (1) 45', both natural and logistic. There is also a table of proportional parts for every integer from 44 to 4300. These tables, except the last, seem to have been published by Burnet.

1721. In this year was printed at Pekin, by command of the Emperor Kang-Hi, in Chinese type and in three folio volumes, Vlacq's logarithmic tables of sines, &c., to ten seconds, and of numbers to 100,000. (Brunet, from Vega, who had seen it in Vienna.)

1741. Depariieux, 'Noueaux Traite de Trigonometrie Rectiligne et Sphrique,' Paris. Depariieux is so much better known by this work that all the following authors are neglected. The tables are all to seven decimals (though the decimal point is not used). There are logarithms of numbers 0 (1) 20000; sines, tangents, and secants, &c., 0 (1) 45' 45' 45', and logistic of the trigonometrical parts has a separate title, 1741, 'A Triangular Canon Logarithmic,' London. Six-decimal logarithms of sine, tangent, and secant 0 (1) 45'. As far as appears, this table was got up by J. Seller and C. Price, mathematicians in the King's service, who have not scrupled to sell their own table of logarithms as well as their own quadrants.
menètes et perfectionnes dans leur disposition par M. Callet.' Callet added as much of each kind of table as would leave no white in his last page, and, from Mouton, completed the single-second table of sines and tangents up to 2°. Here also firm (in hand, method, tables), a manuscript volume containing sines to every second, to how many places does he not say; shortly afterwards he sent the tangents. Lalande gives a hint that the approaching publication of Taylor's logarithms prevented any steps being taken to print these. He also states that there was in the library of the Academy of Sciences a manuscript of Mouton, giving the logarithmic sines and tangents of 0 (1°) to 11 figures; we suppose he means to ten places of decimals. M. Robert's manuscript came into Delambre's possession, and was bought at the sale of his books by Mr. Babbage, in whose possession it now is. It is in two large folio volumes, the figures (to seven decimals) being given in fraction of columns. Some corrections of Callet, discovered by means of this manuscript, were printed in one of the Nautical Almanacs.

1794. George Vega, 'Theorum Logarithrorum completus, Leipsic, 1812,' page 1 and the following pages, contain an account of common logarithms 1 (1) 10,000, distributed in the common manner, a decade in each line, with the differences arranged in the same way, and tables of proportional parts for the first three figures of each. Logarithmic sines and tangents to 10 decimals, 0 (1°) 2° (10°) 45°. Since 0 (1°) 12° to ten decimals. Lengths of arcs to 11 decimals. Wolfram's hyperbolic logarithms above described, reprinted from Schulze. 1794. J. G. von Nordmann, 'Logarithmisch zur Auffassung kauflännischer Rechnungen,' Commercial logarithms. The plan is to have logarithmic tables for integers and different sorts of fractions, among which eighths, tenths, sixteenths, and sixtieths are conspicuous. But it will not do: Mohammed must go to the mountain. When coinage, weights, and measures, are decimalized, the use of logarithms will follow as a matter of course. It is useless trying to bring logarithms to ordinary fractions.

1799. J. P. Robert and L. Ideker, 'Nouvelles Tables Logarithmiques calculées pour la Division décimale du Quart de Ceracle,' Berlin. Delambre speaks highly of this table; but he is surprised to see it reduced, more particularly as those which himself and Borda published. Meaning by 1° the hundredth of the right angle, and 1' being 0°01, and so on, Robert and Ideker's division of the quadrant is 0° (1°) 15° 15° 30° 45° 60°; but Delambre says, 'Robert's, which if not given correctly in our last article, is 0 (1°) 5° (1°) 3° 10° 45° (1°) 60°.' The Berlin table gives sines and tangents and their logarithms, through the quadrant; the Paris table gives logarithms only. The former has no logarithms of numbers except 0 (1) 100 and 999 9980 (1) 100 0021, all to 36 decimals.

1802. J. R. Taschemacher. 'Tables calculated for the Arbitration of Exchanges, both Simple and Compound,' London. This is a book of commercial logarithms, though the author wisely avoided frightening the merchant by mentioning in his preface of his book, it is one table of logarithms for the exchange between London and each other place: the tables average about a page each. With this limited range, the logarithms are really effectively applied, and throughout so simple that they are simplified. We are fully of opinion that such a work might be very useful.

1806. Thomas Whiting. 'Portable Mathematical Tables,' London. This is in two parts. This book, it is one table of logarithms for the exchange between London and each other place: the tables average about a page each. With this limited range, the logarithms are really effectively applied, and throughout so simple that they are simplified. We are fully of opinion that such a work might be very useful.

1808. Ebert. 'Adriani Vlacq Tabulae Sinuum,' Leipsic. The contents are as before described. This is a new (and apparently the last) edition of Ebert's, whose preface is dated 1790. Besides the contents above described there are squares and cubes of all integers up to 1000.

1809. George Douglas. 'Mathematical Tables,' Edinburgh. A long preface; followed by seven-decimal logarithm tables from 1 to 10,000, and these with differences. Two supplemental tables, with the same from 10,000 to 11,000, and from 100,000 to 101,000. A complete logarithmic canon for minutes, to seven decimals. A corresponding canon of natural sines, &c. Natural and logarithmic versed sines, the latter continued to 10°. A table to convert secants into decimals; and logarithms from 1 to 180°, to 15 decimals. A different arrangement from the usual one in several respects.

1812. In Zach's Monatliche Correspondence, vol. xxi, page 498, Gauss proposed his logarithms for the finding of log (a ± b) from log a and log b (Logarithmen, Gauss's, P. C. S.) with a specimen. He stated that he had the habit of using five-figure tables of his own construction. Gauss has given a short review of Paquich's tables (next mentioned) in the 'Gottinger gelehrte Anzeigen,' 1817, No. 158.

1817. J. Pasquich, 'Tabule Logarithmico-Trigonometrice contracta,' Leipsic. Title and explanations in both Latin and German. Five decimal logarithms of numbers 0 (1°) 10,000; logarithms of sines and tangents 0 (10°) 56°; five decimal logarithms of sines and tangents, with a table of the squares of sines and tangents 0 (1°) 45°; Gauss's logarithmica. (Logarithmen, Gauss's, P. C. S.) A recent edition of these logarithmic tables, with logarithmic and trigonometric squares of sines is, we suppose, almost unique.

1817. C. F. W. von Neumann, 'Der Logarithmus in Beziehung auf die Zahlen der ersten 45°,' Leipsic. Gauss's logarithms in existence. It is to seven decimals, and A proceeds as follows: 0 (0001) 2 (0001) 3 (01) 4 (1) 5 (1). 1819. Nordin, 'Adriani Vlacq Tabulas,' &c. The explanations are given in Latin and German. To the contents of Ebert's edition are added square and cube roots to seven decimals for all integers up to 1000. This is called the twelfth edition, which very likely it is; but it was the editor's duty to have stated what the other nineteen editions were.

1821. Westphal's tables, Leipsic, contain Gauss's tables, to five decimals, with proportional parts.

1821. Matthiessen, 'Gemeine Logarithmen,' &c., Altona. Stereotyped. This table has five-figure logarithms from 1 to 10,000, with a supplemental table of proportional parts, arranged on the two sides of a folding sheet, on canvas.

1823. Encke's four-tables of Logarithmica, &c., Berlin, contain Gauss's tables. See '1824, Wartenberg,' below.

1824. J. P. Gruner, 'Beschreibung Logarithmische Tafeln,' Berlin. A second-hand copy. Berlin. Five decimal logarithms of numbers 0 (1°) 10,000; squares and cubes, square and cube roots 0 (1°) 1000; arcs of the circle; logarithmic sines and tangents 0 (1°) 45° (1°) 60°. 1825. H. G. Köhler, 'Tafels Logarithmum,' &c. An edition of Lalande which gives Gauss's logarithms.

No date. (stereotyped.) Moritz von Prasse, 'Logarithmische Tafeln,' edited by Mollweide, and then by Jahn, Leipsic. Five decimal logarithms of numbers 0 (1°) 10,000; of sines and tangents 0 (1°) 45° put together in a new way, so as to separate the common figures, in the logarithms of numbers, and to get five degrees into a double page, sacrificing the differences. Gauss's tables, A, having, 0 (01) 3 (01) 4 (1) 5 (1); and a modification of Gauss's table, in which log x is the argument, and log (x + 1) the tabular result, x going through 382 (001) 2 (001) 3 (01) 4 (1) 5. An edition of Von Prasse was published by Halma, at Paris, in 1814; and the last-mentioned tables was published separately by Weldenbach, Copenhagen, 1829.

1838. G. B. Airy, 'Appendix to the Greenwich Observations, 1837.' London. A table of sines and cosines, with the arguments given in degrees, minutes, and the right marked. There is a separate table both of sines and of cosines, each of which is therefore a transformation of the other. And each again is the table from 0 to 8° repeated, with transformation, for four times; so that the whole consists of four tables, each representing one table. It is to five decimals, without differences.

1839. Anonymous (Useful Knowledge Society). After the first tirage, the following addition was made:—One page,
To our old tables of interest we have to add the following. Stevinus, in the 'Practique d'Arithmetique,' appended to his Arithmetique, Leyden, 1644, reprinted by Albert Girard in Stevinus's 'Collected Works,' Leiden, 1625, gave the following tables of compound interest and annuities. They precede the famous tract La Disme, in which decimal fractions were first proposed. And as this Practique should rather have been at the beginning than at the end, if rational arrangement had been studied; and if the Disme again should have preceded it, on the same supposition; we must infer it to be most likely that the tables were placed in the order in which they were published. In this case, there is every certainty that these tables of compound interest suggested decimal fractions, the account of which speedily follows them. They are constructed as follows:

Ten millions being taken as the base (which calls it), and a rate five per cent, being chosen, the present value of ten millions due at the end of 1, 2, &c., up to 50 years, are put in a column, to the nearest integer. By their sides are the sums of their values, which give the results of all the annuities of ten million, as follows:

<table>

The rates are from 1 to 16 per cent., and also for 1 in 16, 5, 10, 12, 15. At each, in 12, &c., to 1 in 22; or, as the French say, denier quinze, denier seize, &c. At the end is a direction to dispense, when convenient, with some of the last figures.

There is then a virtual use of decimal fractions preceding the formal one. The same thing happens in the tables of Richard Witt, mentioned in our former article, which we believe to be the first English tables of compound interest, and the first English work (except a translation of the Disme of Stevinus) in which decimals were used; the use of them being something more than the virtual use by Stevinus in the Practique. The next English writer who gave tables of compound interest, Robert Butler, in his Scale of Interest, London, 1633, makes a rather more decided use of these fractions than Witt, and uses the phrase decimal fractions, which had then hardly found its way into books. It should be noted that both Witt and Butler give real half-yearly and quarterly tables, as well as yearly ones.

Mr. Pocock, in his Bibliography of Annuités, &c. (Familiar Explanation . . . of Assurances upon Lives, London, 1643), gives the following works, which we do not remember to have seen:—'Tables of Leases and Interest . . .', London, 1628, 12mo.; and William Purser, 'Compound Interest and Annuities, containing the Art of Decimal Arithmetick,' London, 1638.

In Newton's Scale of Interest, mentioned in the list of logarithms, is a set of tables for six per cent., then the maximum legal rate. There is here what we never meet with elsewhere—'the angle of compound interest, with several examples, from some sänt days' having, in lieu of astronomical information, simple and compound interest and discount tables, telling for each day the amount of one pound from the beginning of the year, or the present value for the end.

The first edition of Smart's tables, the original of all our large tables of compound interest, is 'Tables of Simple Interest and Discount at 5, 4, 3, 2, 1, 0, and 1/10 per cent. Poor Ann.' also tables of annuities, interest at the same rates, whereby, &c. By John Smart, at the Town Clerk's Office, London: London, 1707, 4to. (duodecimo size). The second edition, of 1726, is as large, compared with the first, as the table of its author 12mo. of Guildhall, Gent. may have become, compared with the subordinate at the town clerk's office. The first edition which we did not know of when we wrote our last article would find all modern writers knew as little), besides a smaller range of rates, has not the half-yearly, and has only six decimal places. The tables of simple interest are also of very little extent. This set of tables has been incorporated in his Acnowledgments in the article Interest in the second volume of Harris's Lexicon Technicum, London, 1710. There was an abridged edition, with some of the rates and of the half-years left out,

To be seen the Bibliography of Arithmetical works, by the author of this article, intended for the use of the Association for the Advancement of Learning.

Since this was written we find that Mr. Farr (Reg. Gen. Rep. 1644, p. 407) mentions the edition of 1725 as the second edition.
but still to eight figures, 'Tables of Interest, &c., abridged for the use of Schools, in order to instruct young gentlemen in the use of Decimal Fractions,' by John Smart, &c. Leandor's 'Tables of Sines and Tangents,' &c.

Commercial tables of any real power are rendered impossible in practice by the use of shillings, pence, and farthings, except by an extent of matter which makes them very unimportant to the people that use them. The parts of a pound [Computations, P. C. S.] were well correlated and properly used, some of the older tables, which have fallen entirely into oblivion, would certainly be revived with either more labor or less accuracy. These tables could certainly be reprinted when the time comes; Brown's 'Arithmetica Infinita,' and Webb's 'Tables for buying and selling Stocks.' The main part of the former is the first nine multiples of the decimal, which express the number of farthings in a pound. Thus, under 7s. 8d. are 3854166... and its multiples up to nine times. The latter has the multiples necessary to find the quantity of stock which awant to any sum of money, and nice error, at different prices. These are both pocket tables, and their places are supplied at present by works of much greater bulk and less extensive use.

We go a little out of our way to mention Mr. Edward Sang's 'Assurances and Annuity Tables,' Edinburgh, 1841, folio, a most extraordinary work. The author learnt to print that he might set it up with his own hands, and caused the distribution of the whole with the care used in composition. It contains for a single life, and for the Carlisle tables at 3 per cent., every thing. All annuities and assurances, temporary or deferred, or for the whole life, or a part of it, or several lives, or a survivor, or a subsisting period; all the yearly risks of such policies; assurances at increasing or decreasing premiums; five-figure logarithms and antilogarithms, &c., &c., &c. And every result has its logarithm set down by its side ready for use. Why it is so coldly looked at by the assurance offices, those who study the human mind will be no loss to decide. The typography is so beautiful, the paper and type so luxurious, that a century hence a copy will be an object of veneration to the Hebrew and Spencers of that day. We believe it to be a work of great accuracy.

In the preceding articles [Tables, P. C. and the present one] we have described, we believe, all the tables of note, whether in history or practice, as far as general tables of pure mathematics are concerned. We have omitted those which relate only to astronomy, life contingencies, or any other special application of mathematics. Altogether, we have brought forward about 318 tables, of which 221 have been taken from actual inspection, and the remainder from various catalogues and other works. At the end of each of these tables is a notice made to the eye by the 7th of La Place's Bibliographic Astronomique there are 208 tables mentioned, including astronomical ones. In the Royal Society's Library the entries under tables, of every sort, marked by the symbol, are classified by the council of the college, &c., &c., &c. are 563 in number, including from the nearest title-date for one year up to the largest body of logarithms. And upon looking at the appearances which the different catalogues present, we do not find one in which 200, or even 100, tables of pure mathematics are mentioned as having undergone the actual inspection of the compiler. It would not, then, we suspect, be a very extensive undertaking to make as complete a list of tables of all kinds as can now be recovered; and the undertaker of it might expect to be able to verify about two out of three from inspection.

TACK is the technical term in Scotland for a lease, which is the rent called the tack-duty, and the tenant the tacksman. The Scottish system of leases having lately attracted some attention, and being intrinsically important, a separate sketch of its more prominent peculiarities seems desirable. A lease is a contract, which is subsisting or has subsisted for a limited period, called the duration, is purely a contract, and does not paralect—at least in questions between landlord and tenant—of the peculiarities of the feudal system. In early times it is possible to trace something of the nature of the obligation, in which the tenant is bound to the landlord. In Scotland, however, there was no permanent interruption or suspending of the contract; and thus all descriptions of permanent estates could be constituted in the land by the pure adaptation of the feudal usages. There was no temptation to convert the contract for the limited occupancy and use of the land into a means of constituting a semi-

proprietary right in it—of supplying with a lessee the place of a sub-vasal; and the system of leases, as one of mere letting and hiring, took its principles from the Roman contract of locatio conductio, with the right of the lessor to have the use of the land, so purely personal that it was ineffectual against a party acquiring the lands by purchase from the lessor; and so early as 1449 a statute was passed, preserving the rights of the lessor, when the tenant had conveyed the leasehold right, however, in questions of succession, and in the form of attachment, employable by creditors, have by usage come into the position of real or heritable property. In the civil laws, on the other hand, the tenant of a lease, such successions follow the rules applicable to landed property. It has been matter of much regret, that the system by which feudal rights in land may be subjected to real burdens, has not been extended to this species of property, so as to enable valuable leases to be burdened with a security for borrowed money, or a guarantee fund for provisions for children. The system of granting and recording public feudal titles not being available for this species of property, all attempt to accomplish this object, by the tenant assigning the lease and retaining possession as the assignee's sub-tenant, have been ineffectual against the rights of creditors. It has been frequently proposed to pass an act creating a system of registration of leases, and of burdens affecting them.

It is unnecessary to state very minutely the title which a person who has a right to grant a lease, or parties who may hold leases, or the nature of that title which constitutes an ordinary lease, as these bear a generic resemblance to the corresponding features of English law. Long leases however being the prominent feature of the Scottish system, those cases in which there is a restriction on granting them may be noticed. A person who has a life-rent interest is, in the general case, not entitled to grant a lease to last beyond his own life. Persons having the absolute administration of property, as trustees, corporations, &c., are entitled and bound to grant leases for such a period as is deemed necessary to good husbandry; and this period has, by usage, in the ordinary case, been fixed at nineteen years. There have been many questions as to the extent to which persons holding under entail may grant leases, because in many instances attempts have been made in this form to alienate a considerable estate in the property, which has been an argument for granting leases to successors. In the celebrated Queenberry case, leases granted for ninety-seven years, on a grasmun (that is, a sum of money paid by the tenant on entering, like a fine in England), at the rent struck by the vendor when he was at the Launceston, were found to be in the possession and power of the landlord, and could be alienated as a part of the property (2 Dow, 90). In later cases, leases of forty and thirty-one years have been found ineffectual.

A lease of twenty-one years is the longest that has been sanctioned an heir of the soil, and Mill has shown that he has an interest to impugn the contract.

Writing is necessary to constitute a lease, although possession during the part which may remain over of a year begun, may be held as a right from suffranchis and acquiescence in its commencement. The proper form of the written agricultural lease has been an object of much attention by conveyancers, and there is a considerable degree of uniformity in the practice throughout the country. There are usually nineteen clauses, as follow:—1. The Description of Parties. 2. The Destination, in which the extent to which assigning or subletting is permitted or prohibited is set forth, and provision is made for the arrangements in case of death of either party. 3. Clause of Possession, describing the subject let. 4. Duration. 5. Reservation, if there be any rights such as that to minerals or game reserved by the landlord. 6. Landlord's Meliorations, concerning such as he may be bound to make to improve the subject as the landlord undertakes. 7. Warranties, or guarantee of the title given to the tenant. 8. Rent clause. 9. Tenant's Meliorations, setting forth such improvements as the tenant has not agreed to undertake. 10. Treasurer's accounts, containing provision to keep the building, fences, &c. in repair. 11. Insurance, in which the tenant becomes bound to insure the buildings, crops, &c. against fire and storm. 12. Rightlet, the clause, &c. are now comparatively seldom found by the tenant to bind the tenant to grind his corn at the mill of the over-landlord. 13. Management. 14. Bankruptcy, providing in general for the landlord's resumption of the lease if the tenant becomes bankrupt. 15. Removal, by which the tenant engages to
TEN

606

TAI

evacuate the premises at the prescribed term. 16. Reference, providing for arbitration of disputes. 17. Mutual Performance, indicating penalties to be paid by the party failing. 18. Performance (in varying forms, T.C.S. 31). 19. Tenancy clause, containing the formalities of the execution of the contract. Of these, the clause of management is the most important. It is now much doubted how far it is good policy to subject the tenant to the observance of a particular course of agriculture. In the highly improved districts, where very scientific farming is expected, the tenant is generally more capable than the landlord of estimating the value of improved agricultural chemical cultures. 20. Landlord. 21. Borristy and Life, the grass, 22. England. 23. Frames and Tenantry. 24. Family, the one. 25. The expected, It shall be the rule. 26. Generally, that the grass, a long, and reach to the base of the cu. 27. The ventrals are moderately developed. The Cepola rubescens, a beautiful species, of the fins. 28. The true horse, is occasionally found on the southern coasts of Britain. 29. The genus Lophotes of Giornia has a short head with a bony crest bearing a long and stout spine. The caudal fin is differentiation genus. In a list, and, shark in domestic use, it is often found of the southeastern coasts of Britain. 

TAGORE, DWARKANATH. [RAMMOWUN Rot, P. C. S.]

TALEZIE, in the law of Scotland, is the technical term corresponding with the English word Entail, which now generally superseded it in colloquial use, even in Scotland. The early history of Entail law in Scotland in some respects resembles that of England, in later times they diverged from each other. In Scotland there was no early effort, such as the statute of Westminster the Second (13 Edw. I.) to favoring that是什么？

TENIOTTERIS, a group of fossil forms with broad ribb-
coming to pass, should cause a nullity. (Duffin’s Travels v.
Dunkar, 28th January, 1844, 4 D. B. M. 523.) Some
statutory enlargements have been made on the powers of
parents to provide as best they may for the
younger children: but the system is still productive of great
domestic inequality, and it is to be hoped that in no long
time it will be swept away as an impediment to the improve-
ment of the country and an injustice to the mercantile
classes.

TAJRURAH is a sea-port in Africa, situated at the most
western corner of the Gulf of Aden, in 10° 47’ N. lat. and
43° E. long. It is built on a low shore of sand and
silt, which extends several miles farther west, and is called
the Bay of Tajurrah. The anchorage is of moderate extent,
and large vessels must remain at some distance from the shore.
It is secure, except during the north-western monsoon, and
is situated near the island of Jezirah, which is 30 miles
west of the island of Shoa. (Adams, P. C. S., p. 20.) These articles go
chiefly to Mocha and Hodeida; to Aden wool, sheep, goats,
and butter are sent. There is no bazaar in Tajurrah, but the
commerce is conducted through small market-stalls, with
beads, buttons, fish-hooks, and tobacco. Water is plentiful,
but grass is scarce, and fodder for horses is obtained with
difficulty. The climate is very hot; during the last days of
May and June the market is at its height, and the goods
are purchased and the money changed at the time of
the chief of the whole nation. None of the Dandali tribes pay
obedience to his orders, but they send him annually a present
of two hundred head of cattle and camels. As this town is
the nearest port to Shoa, and the British have entered into
a closer connexion with the sovereign of that country since
their occupation of Aden, it is hoped that Tajurrah will soon
rise to greater importance. The British have also made a
 treaty with the Dandali and Somalul, and have acquired two
larger islands, situated near the entrance of the Bay of Ta-
jurrah, and a smaller one which lies farther within the bay;
but we do not know if they are actually taken possession
of.

(Iseenberg and Kräf t’s Journals, detailing their proceedings
in the Kingdom of Shoa; &c.; Kirk’s Report on the Route
from Tajurrah to Anodak; The Friend of Africa, 1841.)

TALLOW (French, tallow; German, talle; Italian, sebo;
seco; Russian, sedlo, toplomos; Spanish, sebo) is animal fat
[Fox, P. C., p. 204] melted and separated from the fibrous
or membranous matter which is naturally mixed with it.
When pure, tallow is white, and nearly tasteless; but the
tallow of commerce usually has a yellow tinge. It is di-
vided, according to its qualities, into various kinds, of which
the best are used for the manufacture of candles, and the
inferior for making soap, greasing machinery, and some other
purposes. Much tallow is used in the dressing of leather.

A very large proportion of the tallow used for making
candles in this country is supplied to the market, and acco-
Accomplished to a paper on ‘Artificial Light from Solid Substances, and the
Manufacture of Candles,’ published by Arthur Alkin, Esq., in the fifty-second volume of the ‘Transactions’ of the Society of Arts (part ii., pp. 153-127), is fitted for use by the renderers,
who chop into pieces the fat and meat received from the
butchers, and boil it in water, by which operation the
greater part of the fat is melted out from the membranous
ducts to the top of the meat. The remaining
fat is subsequently squeeved from the membrane by a
powerful press, leaving the membranous matter in the form of
a sheet or block, of a dark colour, which is called gyros,
and which is destined for the manufacture of soap. This
becomes a wholesome and palatable article of food
for poultry, dogs, and other domestic animals. It is said to
be extensively used in fattening poultry for the market. Dr.
Ure, in noticing this subject in his Dictionary of Arts, &c.,
calls ‘Tallow Candle,’ styles the refuse membranous matter crackerings;
states that the operation of rendering should be performed
as expeditiously as possible, and does not manage it
without the presence of young children; but the system is still productive of great
domestic inequality, and it is to be hoped that in no long
time it will be swept away as an impediment to the improve-
ment of the country and an injustice to the mercantile
classes.

Almost all our imported tallow is brought from Russia,
where this article is produced in enormous quantities. Kohl,
in his work on that empire, gives a graphic account of this
great branch of industry, and describes its manufacture in the
translation, published in Chapman and Hall’s Foreign Library,’
1842, pp. 501-503), we conclude the following par-
ticulars:—The exports of St. Petersburg, he states, are
estimated to amount to 30,000,000 lbs. annually, or
adequate; the tallow is strained through a sieve into a second copper, and
there treated with water at a boiling temperature of 120 lbs. in
weight, and is then thrown into the boilers, where it is allowed to
remain for four to six weeks, so that the tallow is rendered
the rest of the world, providing the chief supply of soap and candles to
England, France, Germany, Scandinavia, Italy, and the other
countries of Europe; and the article is in addition to the large
quantity consumed by the Russians themselves. Nearly
the whole of this enormous quantity is furnished by the
stage steppe, in the southern part of European Russia. ‘At
present,’ he observes, ‘the great tallow, or Bark Slack, is
furnished by the natives of Great Russia, who have their establishments in all
parts of the steppe. ‘They buy the cattle by hundreds and thousands, and after
transporting them through the steppes, they are sold for
the salgans, as they are called, or exclusively in the hands of the
natives of Great Russia, who have their establishments in all
parts of the steppe. ‘They buy the cattle by hundreds and thousands, and after
transporting them through the steppes, they are sold for
the salgans, as they are called, or exclusively in the hands of the
natives of Great Russia, who have their establishments in all
parts of the steppe. ‘They buy the cattle by hundreds and thousands, and after

part
A further supply of fat, but of very inferior quality, is sub-
sequently obtained by subjecting the mash of bones and flesh to
fusible processes. This tallow, which is rarely exported, is
of a dark brown colour, and is used for greasing wheels and for
other coarse purposes.

An ox in good condition, it is stated, will yield from
seven to eight pounds (250 to 290 lbs.) of tallow, which is
generally worth from eleven to fifteen rubles a pound. The
article is always so greatly in demand, that the merchants often
pay part of the price for it while the oxen are yet grazing
on the steppes; and the singular appearance of the salgans
is heightened by the number of merchants and their clerks in
attendance upon them, for while the status of the salgans on
which the oxen have fattened comes to receive his rent; the
workmen for their wages; cattle-dealers to contract for fur-
ther supplies of oxen, while perhaps some merchant is standing
by, equally secure and assured in advance for the tallow
that is to be produced by them; and a colonist comes in to bargain
for the fattening of some 200 hogs, which he afterwards
receives back walking masses of hog's-lard, too yellow and
crude however for the market, till the grutters have been
a little refined by sundry good foods of corn. Sometimes
a wealthy nobleman, possessing oxen, but no tallow-making
establishment of his own, makes his appearance to form a
salgan for a few weeks, while other persons, having no
means to buy the refuse-meat for feeding pigs on the steppe, or to
bargain for the hogs and hides.

The Turkish captains come eagerly to obtain the tallow in
its greatest purity at the fountain-head, for tallow is too much esteemed by the Ge-
mans of Constantinople to be idly wasted in enlightening their
darkness; in short, however hastily death may be at work,
there is, meanwhile, no want either of life or blade in the
salgans.

Notwithstanding the nature of the employment, there are
always plenty of hands found to seek engagements in the
salgans, the wages being high. The workmen usually earn
about one ruble per month during the winter, which is
about two or thirteen weeks. In the neighbourhood
of Odesa, Kohl states, there are seven salgans, in which pro-
ably 25,000 oxen are killed every year, besides countless
sheep. In the vicinity of Nikolayev, Saratoff, Kihneff, and other places, he adds,
their number will be found on an equal large scale.

From details quoted in M'Culloch's 'Dictionary of Com-
mmerce', by Burnow of St.

Petersburg, it appears that the merchants of that city divide the
tallow which they receive from the interior into white
and yellow candle-tallow, and common and Siberian soap-
tallow; the latter, which is considered the best tallow for
soap-making, being brought by several rivers from Siberia to
the lake Ladoga, and thence to the Neva by the canal of
Schlusselburg. An emballage, or warehouse, is appropriated to
the reception of the tallow on its arrival, in which it is
selected and assorted (or bracked) according to quality, after
which the casks are marked with the quality, the date of the
selection, and the name of the bracker or selector. The
weight of the tallow usually brought in coastal casks, 24 feet
in diameter at the largest and 14 at the smallest end; but
the yellow tallow is commonly in casks of the more usual shape.

'Tallow-candle-tallow, when good,' according to this author,
should be clean, dry, hard, when broken, and of a
fine yellow colour throughout. The white candle-tallow,
when good, is white, brittle, hard, dry, and clean. The best
white tallow is brought from Woronouch. Soap-tallow
should be clean, strong, and of a fine yellow tinge throughout.
M'Culloch states that 120 poods of tallow, gross weight
(of which the cask is usually about 10 per cent.), make a Peters-
burg last, and 63 poods an English ton.

A great many articles are prepared from the tallow, but
the practice of mixing different kinds of tallow together according
to different requisitions for the mixture; but it is stated in the article *Candle* in the
Encyclopaedia Britannica, that one-half of sheep's and one-half of bullock's tallow should be used, and that hog's
tallow is inferior, as it saponifies less readily, and is fit for
beeswax, give an offensive smell, and produce a thick black
smoke; and Dr. Ure states that *mutton-ox*, with a propor-
tion of ox-tallow, is selected for mould candles, because it
fills them more closely and consistently. When weighed in
the proportions, and cut up into small pieces that it may melt
more readily, the tallow is, according to Alkin's account, put
into a boiler with some water, which tends to prevent its
formation of small globules, and melted a small pavement of about
90°. Some water is then sprinkled upon it, which has the
effect of causing such drops and impurities as may have escaped the skimmer to sink to the bottom, after which the
clear tallow is let out by a spout into suitable receptacles,
and, when sufficiently cooled, but while yet retaining its perfect
transparency fluidity, it is fit for use. Different kinds of tallow
melt and retain their fluidity at very different degrees of tem-
perature; the fat which is deposited about the sinews being
in all animals, harder than that found in the cells of the bones;
and especially that half of the fat found in the muscles and
other soft parts; while the fat of some animals is harder than
that of others, and it has been found that oxen are much
more likely to melt than that of the ox or horse. According
therefore to the different kinds of fat which may enter into
its composition, tallow will be found to vary considerably in its
temperature of melting, and its fluidity. For instance, the
best point, though Alkin states that he had seen a boiler-full of
tallow perfectly fluid at 70°, and even then not sufficiently
cooled to be made into candles; nor was this case, he observes,
considered remarkable; whereas we may conclude that tallow,
made into candles and exposed to the air, loses much of its
fluidity. The author of the article above referred to in the
Encyclopaedia Britannica, observes that no water should be
mixed with the tallow, nor any mixture with the oil, or with
the wicks, being quite dry, should imbibe it, and thus cause the
wicks to spatter in burning. He adds that in removing the
melted tallow from the boiler to the tub or vessel in which the
wicks are dipped, it may be passed through a coarse horse-
hair sieve, to purify it the more perfectly; and that it may be
used after standing three hours, and will continue fit for use
about twenty-four hours in summer and fifteen hours in winter.

The mode of manufacturing both dip and mould candles
being described under CANDLE. P. C., p. 236, we need only,
upon this subject, refer to a fuller account of the process,
illustrated by the directions given in the article. A very
employed in an extensive candle-factory, including one by which
the operation of dipping is so facilitated as to enable a man
and a boy to make nearly 26,000 candles, of twelve to a
package, in twenty-four hours, or a day, in the afternoon, in the
*Penny Magazine*, No. 631, description of

'A Day at a Soap and Candle Factory.'

'A recently made candle of good quality,' observes Alkin,
"is of a good fine, close, and even white, of a fine yellow
colour, which is the true colour of some of the best tallow,
which is not dry enough to be taken up by the wick. It is
necessary to put it a little into a vat of brandy, and
keep it there a little while to make it more dry; then
sputter when set fire to, and give to a comparatively feeble
light, the two latter qualities showing that it contains a little
water. If kept three or four months, he proceeds, 'in a
box placed in a cellar (for the presence of the sun's rays is
by no means necessary), the candle will be found bleached
both inside and outside, will be harder than at first, and
will then burn with a clear flame undisturbed by any spattering.
It is evident therefore that the water has been evaporated
and it is also extremely probable that the water, or the air
which the water holds in solution, has acted chemically on the
tallow, bleaching and at the same time hardening it.'

This bleaching process, he adds, 'goes on slowly in a cold
and damp atmosphere; it being found that autumn-made candles
hardly ever bleach to a good colour, although in three or four
months they are fit for use. Candles made in March bleach
the best of any, for the three or four months during which
they are kept in the manufacturer's store are usually dry and
warm.'

'Tallow-lamps, as well as some recent improvements in
the manufacture of candle-lamps, are treated of under Lamps, AVTIP-
P. C. S., p. 263.'

TANACETUM, a genus of plants belonging to the
natural order Compositae and the sub order Corymbiferae. The
flowers are usually white, yellow, or purplish; the receptacle
is imbricated, the receptacle naked, the fruit oblong and anga-
This act reduced the duty on about 750 different articles on which the receipts had amounted to about 270,000. The general principle of the measure was to reduce the duty on raw materials to about 5 per cent., to limit the highest duty on certain manufactured articles to 12 per cent., and on complete manufactures to about 20 per cent. The number of articles in the tariff was now reduced to 818. Foreign horned cattle, sheep, goats, swine, salmon, sole, and other fish, and fresh beef and pork, which had been prohibited formerly, were admitted on paying a duty under the tariff of 1842. In 1844 the duty on foreign wool was abolished. In 1845 Sir Robert Peel effected further improvements in the tariff by abolishing duties on most raw wool (about 80,000), and on 480 other articles, on which the duty amounted to 390,000. By this plan expenses of warehousing are saved [Warehousing System, P. C.], and a number of troublesome and impeding acts in businesses, but for statistical purposes the customs department retains the power of examining articles which do not pay duty. The paramount object of the tariff reform of 1845 was to encourage the abundance and cheapness of raw materials of manufacture. In the same year, by an act (8 Vict. c. 7) to repeal the Duties of Customs due upon the Exportation of certain Goods from the United Kingdom, the duties on cheese, calves, etc., were wholly repealed. Caps. 84 to 94 of the 8 & 9 Vict. are all acts relating to Customs, Trade, and Navigation, and they all came into operation on the 4th of August, 1845. Cap. 84 is 'An Act to repeal the several acts relating to Customs. 30 acts relating to Customs, Trade, &c. of which 26 acts were repealed. Cap. 85 is 'An Act for the Management of Customs, and regulates the appointment and duties of officers, the taking of land for warehouses, &c. Cap. 86 is 'An Act for the Registration of Customs, and relates to landing, warehousing, and custom-house entries. Cap. 87 is 'An Act for the Prevention of Smuggling,' and specifies the acts which constitute smuggling, and the penalties. Cap. 88 is 'An Act to repeal the several acts relating to Customs, and imposes duties upon certain articles. These duties are referred to in the preamble of the Tariff (9 & 10 Vict. c. 23) hereafter mentioned.' Cap. 89 is 'An Act to regulate the Trade of British Possessions abroad. Cap. 94 is 'An Act for the Regulation of the Trade of the Isle of Man.' On the 26th of June, 1846, the royal assent was given to Sir Robert Peel's last tariff, which carries out still further the principles of freedom of trade, produced 38 acts. The following table of the tariff of 1833, showing the duties received in 1838-9, is an analysis of one prepared by the inspector-general of imports for the parliamentary committee to which allusion has been made:—

In 1842 Sir Robert Peel effected some improvements in this system, which were carried into effect by 6 & 6 Vict. c. P. C. S., No. 162.

Wheat, per quarter, under 48s. | 10 | 48s. and under 49s. | 9 | 49s. and under 50s. | 8 | 50s. and under 51s. | 7 | 51s. and under 52s. | 6 | 52s. and under 53s. | 5 | 53s. and upwards | 4 |

22s. and upwards 1 6

On rye, peas, and beans the duty is equal in amount to the duty payable on barley. But there appears to be some bilateral action on rye, peas, and beans being regulated by the duty on barley, is regulated by the price of barley, and not by the price of rye, peas, and beans. The consequence of this is that the duty on barley is 26s. the quarter, and is paying 5s. duty, rye, peas, and beans will pay 5s. duty, whatever their respective prices may be; and they will only pay the lowest duty of 5s. per quarter when barley is 31s. and upwards the quarter. (See 'Economist.' Newspaper, June 4th and 11th, 1846.) The duties payable on all flour and meal, as above enumerated, until the 1st February, 1846, are enumerated in the schedule to the act. The average price, both weekly and quarterly, of all British corn, to continue to be made up according to 5 & 6 Vict. c. 14.

Of the exemptions from duty and reductions of duty made by the last Parliament (9 & 10 Vict. c. 22), it will suffice to mention a few of the most important.

No duties are chargeable on the following living animals:—
even and bulls, cows, calves, horses, mares, geldings, colts, foals, mules, asses, sheep, lambs, swine and hogs, sucking-pigs,

No duties are chargeable on bacon, beef fresh or slightly salted, salted, not being termed beef, most fresh or salted, not otherwise described, pork fresh, salted (not hams), potatoes, all vegetables not otherwise enumerated or described, bay, hides, and some other articles slightly wrought, and a few wholly manufactured.

Of the reduced duties the following are the most important:

—ale and beer of all sorts, 1l. the barrel; arrow-root, 2s. 6d. the cwt.; and if from a British possession 2s. 6d. the cwt.; pearled barley, 1s. the cwt.; and if from a British possession, 6d. the cwt.; buckwheat, 1s. the quarter; butter, 10s. the cwt., and if from a British possession 2s. 6d. the cwt.; tallow-candles, 6s. the cwt.; choose, 6s. the cwt., and if from a British possession 2s. 6d. the cwt.; cured fish, 1s. the cwt.; hams of all kinds, 7s. the cwt.; and if from a British possession 1s. 6d. the cwt.; men's hats, 2s. each; men's boots, 14s. the dozen pairs; men's shoes, 7s. the dozen pairs; women's boots and shoes, from 4s. 6d. to 7s. 6d. the dozen pairs, according to kind, as described in the British, or India; currants, 5s. the cwt.; pepper, 1s. the cwt.; rice, 1s. the cwt.; and if from a British possession 6d. the cwt.; sago, 1s. the cwt.; tallow, 1s. 6d. the cwt.

The duties on manufactured goods of brass, bronze, china-
ware, copper, iron, and steel, lead, pewter, tin, woollen, and cotton, are 10s. for every 100l. value. On silk manufactures the duties are about one-third higher, or 5s., 6s., and 9s. the lb., according to kinds, as described, or 10l. on every 100l. value.

The duty on foreign spirits of proof strength is 15s. the gallon.
The duty on foreign solid timber, from and after April 5, 1847, is 1l. the load of 60 cubic feet; and from and after April 5, 1845, is 1l. the load. On deals or boards, the duty, from and after April 5, 1847, is 1l. 6s. the load; from and after April 5, 1846, it is 1l. the load. The Tariff of 1842 is not altered with respect to timber imported from a British possession, which is still 1l. the load of solid timber, and 2s. the load of sawn timber.

The duties on coffee and tea are not altered by the tariff.

Sugar Duties.—On the 18th of August, 1846, the royal assent was given to an Act (9 & 10 Vict. c. 63) 'for granting certain duties on Duties on Sugar, Molasses, and Sugar- On sugar or molasses the growth and produce of any British possession in America, or of any British possession within the limits of the East India Company's Charter, into which the possession of foreign sugar is prohibited, and imported from thence, the duties following:—

Candy, brown or white, double refined sugar, or sugar quality in double refined, per cwt. 1 1 0
Other refined sugar, or sugar rendered by any process equal in quality to white, per cwt. 0 1 8 4
White dyed sugar, or sugar rendered by any process equal in quality to white dyed, not being refined, per cwt. 0 1 6 4
Brown sugar, being Muscovado or clayed, or any other kind not being equal in quality to white clayed, per cwt. 0 1 4 0
Molasses, per cwt. 0 6 3

And from and after the respective days next hereinafter mentioned,—

On Sugar or Molasses the Growth and Produce of any other British Possession within the Limits of the East India Company's Charter——

And also from and after the passing of this Act,—

On all foreign sugar or molasses not otherwise charged with duty, the duties following:—

Refined sugar, or sugar candy, per cwt. 3 5 0
Brown Muscovado or clayed sugar, not being refined, per cwt. 2 2 0
Molasses, per cwt. 1 6 8

TARUNTENUS PATERNUS, a Roman jurist, was Prefectus Praetorio under Commodus, by whom he was put to death. (Lamp. Commod. 4.) He wrote four books De Re Militari, from which there are two excerpts in the Digest. He is mentioned by Vegetius (De Re Militari, 2).
mentioned ranges are separated from each other. This place occurs near 35° N. lat., and between 74° and 76° E. long., between Chitral and Gilgit, where a high mountain-mass, the Turcuan Mutanai, rises to nearly 18,000 feet above the sea-level. At the same time from this point the mountain-mass extends in a north-west by south direction to 45° N. lat., where its northern prolongation is known by the name of Kooy-urt; it lies between 70° and 71° E. long.

This mountain-mass is of great width, occupying between the parallels above mentioned all the countries which lie between 70° and 75° E. long. But we are not exactly acquainted with the limits of this range, nor with the plains on the east and west, as these countries are very difficult of access to European travellers, a few of whom only have reached them. A great portion of these mountains appears to be elevated above the snow-line. This is especially the case with an immense snow-region, which occurs between 35° 30' and 38° 30' N. lat., and which goes by the name of Puchikut. It is considered one of the most extensive snow-regions on the surface of the globe. North of this remarkable region is a depression in the range, in the middle of which is a large alpine lake, called St-i-Kol, in which the river Oxus originates; it runs out from its western extremity. This lake is situated on the crest of a range, and is about fourteen miles long from east to west, with an average width of one mile. On three sides it is bordered by swelling hills, about five hundred feet high, but along its southern banks it rises into a series of snow-covered mountains, which are separated from the plains by a depression of 15,600 feet above the sea-level, their summits attain more than 19,000 feet. North of this lake lies an immense table-land, which is called Pauri, or, in the emphatic language of the native, Pat-i-Dher, in which three parts several large alpine lakes are stated to occur, and which we are not acquainted with their true position, nor with their extent. In 41° N. lat., the Bolor Tagh crosses the mountain range, which is called Dahan Oosteng and runs from west to east. That portion of the last-mentioned range, which lies west of the Bolor Tagh, is called Asferal Tagh, or Ak Tagh, and that on the east Terek Tagh. In these parts the Bolor Tagh appears to be a more elevated range, and it is probable that it connects Chinese Turkistan with Turan; but the mountains even here are always covered with snow. It is also stated that several snow-capped summits occur in the northern prolongation of the range, the Kooy-urt.

In the numerous valleys which open into the adjacent plains, and generally run east and west, different kinds of grain are cultivated. In the valley of Wakan (37° N. lat.), which is grown at an elevation of 10,000 feet above the sea-level, whilst in the Alps it does not succeed in Engadin, at a height of 6000 feet. These valleys are inhabited on the western side by the Kirghiz, the descendants of the ancient Persians. On the eastern declivity they are in possession of a population of Turkish origin, the Kirghiz. They are of the same stock as the numerous tribes which dwell on the same range in the wide desert plains which lie on the east and north of the Aral and Caspian seas. They appear also to be closely allied to the Uzbeks, as, according to the statement of Lieut. Wood, their language differs only in a trifling degree from that spoken in Kanduz. This bold traveller describes these mountaineers as being of a middle size, varying between five feet two inches to five feet five and a half inches in height. Their countenance is disagreeable. The upper part of the nose sinks into the face, leaving the space between their deeply seated and elongated eyes without the usual dividing ridge; the brow immediately above the eye is prominent, but slants back more abruptly than their cheek bones, and is humped, and toed, as if pieces of flesh had been daubed upon them. They have little beard, and with those individuals who have a more luxuriant growth of hair, both beard and whiskers have a curl. The hair of the head is long and thin, and its complexion is darkened by exposure to weather rather than by the sun. The women are rather good-looking, having a small and delicate form and fair complexion. The Kirghiz roam about in this region with their tents, and live mostly on game, fish, and yaks. The men use the does and Lamet. Wood thinks that this mountain-region is the true native country of these animals, which are called Bactrian camels. The yaks still less than the reindeer cannot bear a considerable degree of heat, and live always near the places which are covered with snow. The Kirghiz of this mountain-region acknowledge allegiance to Kokand, and pay a nominal tribute to its ruler, but with China and Tibet they are constantly at feud, and they rob all parties north of 35° N. lat., and it is probably beyond down from this region.

We know very little of the mineral wealth of the Bolor Tagh. Gold and silver are said to be found. In the sand of the Oxus gold is found in abundance, and in some parts of its lower course it is possibly by gold-diggers. Leaving Yarkand it gradually ascends the valley of one of the tributaries of the Yarkling-osteng river, and after passing the crest of the mountains near the lake of Sir-i-kol it descends through the valleys of Wakan (WAKHAN, P.C.S.) and Badakshan to Kunduz. This road does not appear to be much frequented. The northern road runs from Kanghai in Chinese Turkistan to Kokand and Tashkand. After leaving the first named place it follows the valley of the Kanghsirdir, or river of Kanghai to its source, then turns northward, passing over the crest of the Terek Tagh to Osh, in the valley of the Sir-i-diria, and crossing again the northern prolongation of the range, it reaches the Oxus, where caravans pass along this road, and exchange the goods of Chinese Turkistan for those of Bokhara and the other countries of Turan. (Ephraim's Account of the Kingdom of Cabid and its Dependencies; Burnes' Travels into Bokhara; Wood's Journey to the Source of the River Oxus; and Humboldt's Central Asia.)

TAXATION, LOCAL. There was published, under the direction of the Poor-Law Commissioners in 1846, a valuable work entitled 'The Local Taxes of the United Kingdom, containing a Digest of the Law, with a Summary of Statistical Information concerning the Amounts levied, and the sums received, in England, Scotland, and Ireland.' England includes England and Wales, but is remarked in the Introduction that these local taxes are of two kinds: the rates raised in defined districts; and the tolls, dues, and fees paid for particular services or on certain occasions. But those rates only will be here noticed which are authorized by general statutes or the common law; excluding such as derive their origin from commission Acts. The rates are divided into three classes:—I. Rates of independent districts, on the basis of the poor-rate. II. Rates of independent districts, not on the basis of the poor-rate. III. Rates of degrees of ago and common. No. I. comprehends—1. The Poor Rate; 2. The Workhouse Building Rate; 3. The Survey and Valuation Rate; 4. the Jail Fees' Rate; 5. The Constable's Rate; 6. The Highway Rates (these three are paid by the owners of land in the county for the maintenance of the county roadway.); 7. The Militia Rate. No. II. comprehends—1. The Church Rates (three); 2. The Sewer's Rate; 3. The General Sewer's Tax; 4. The Drainage and Inclosure Rates; 5. The Inclosure Rate; 6. The Regulated Pasture Rate. No. III. comprehends—Counts: 1. The County Rate; 2. The Police Rate; 3. The Shire Hall Rate; 4. The Lunatic Asylum Rate; 5. The Burial Rate. Borough Rates: 6. The Hundred Rate; 7. The Borough Rate; 8. The Watch Rate; 9. The Jail Rate; 10. The Prisoners' Rates; 11. The Lunatic Asylum Rate; 12. The Museum Rate. Counties and Boroughs: 13. The District Prison Rates.

The head of Tolls, Dues, and Fees, comprehends—1. Turnpike Tolls; 2. Borough Tolls and Dues; 3. Light Dues; 4. Post Dues; 5. Church Dues and Fees; 6. Marriage Fees; 7. Registration Fees; 8. Justiciary Fees. The following outline of the work published under the direction of the Commissioners, as an approximate summary of the present annual amount of the local rates in England and Wales (p. 178):—

* The 8 & 9 Vic. IV. c. 25, the chief provisions of which act have been stated under BURMSEY, P.C.S., as amended by 8 & 9 Vic. c. 45.
The rates for Ireland are given at £1,631,818, 199,469.

The amount of annual local taxation of Great Britain and Ireland accordingly amounts to 14,197,044/. But it is observed that if the deficient information were supplied, it would appear that in Great Britain and Ireland the annual sum raised by the local and general taxation is about 57,000,000/. a year. The public expenditure for the year ending 31st December 1845 was 49,061,411, of which sum 29,315,672 was paid on account of the Funded and Unfunded Debt. This leaves somewhat under 21,000,000/ for the rest of the general public expenditure. Accordingly the present amount of the local taxation, 15,000,000/ is nearly equal to three-fourths of the public expenditure after deducting the payments on account of the Funded and Unfunded Debt. It is well remarked in the work from which these facts are derived (p. 190), 'When the Local Taxes are brought under review in this collective amount, it then at once becomes manifest how really deserving of serious consideration are the modes of raising and expending them, so as to secure the most efficient and economical management of a revenue, so important a public fund, which derives its importance not only from the largeness of its aggregate sum, but from the extent of the property and the number of persons affected by it, and from the numerous and diversified public objects to which it is applied.'

TAXICORNES. The second family of the heteromorphous coleoptera, in Latrielle's arrangement of insects. They have no cuneous tooth on the inner side of the maxilla; the femora are all winged insects with nearly square bodies, and a thorax which conceals or receives the head. They have short antennae and legs adapted for walking only. They live in fungi, beneath the bark of trees, or on the ground under stones. This family is divided into two tribes, of which the genera Dicoprops and Coexphus are respectively the types.

TAXITÉS, a coniferous fossil genus of plants from Stonefield, Cornwall.

TAXOCRINUS, the last generic name assigned by Phillips to the group of Escrinuna analogous to Taxisornis (Poteriocoris Egerioni). It has several synonyms. (Moeris's Catalogue.)

TAYLOR, WILLIAM, was born at Norwich, in the year 1765. He was the only child of an eminent merchant of that city. He first studied under a Swiss refugee, and afterwards was a pupil of Mr. Bostock, a Unitarian minister, at Falmore, a tutor chiefly selected on account of his religious opinions, which were those of Mr. Taylor and his family. To Mr. Barbauld, better known as Mrs. Barbauld, was indebted, in her early studies; aided by her assiduous care, he soon acquired a correct knowledge of the principles of English composition, and, in after life, he gratefully acknowledged his obligations both to the celebrated woman, whom he styled 'the mother of his mind.' On leaving the house of Mr. Barbauld, at the age of fourteen, he was placed by his father in his counting-house at Norwich, who was desirous that he should succeed him in his large and prosperous business. Shortly afterwards he was sent on the Continent, under the care of one of the partners of the firm, for the purpose of perfecting himself in the French and Italian languages; which were of the utmost importance to the business of his family. Before leaving England, he had already evinced considerable facility in acquiring knowledge of languages; and he had been but a short time abroad when he sent his letters to his parents, in English, French, and Italian, at the early age of fifteen, gave the promise of that eminence as a writer to which he afterwards rose. On his return to his native city, he was encouraged in the prosecution of his business by the sound admiration of his parents and friends; and for the two years he remained there, he appears to have given the tone to its Literary circles. A second tour to the Continent was resolved on soon after; and he spent much of his time in acquiring a familiar acquaintance with its language and literature. A residence of a year at Paderborn was sufficient for this purpose. Under the influence of his perception of a taste not confined to Germany, but for the philosophy of that country: a taste...
which ever afterwards characterized his writings. On his second return to Norwich, at the age of eighteen, his parents perceived that his son had an imagination too lively, and a taste too decided for literary pursuits, to allow him to devote himself to the mercantile profession. The affluent circumstances of the father, added to the gratification which he expected from the prospect of a regular income, the high distinction in letters, induced him to forego the strict accomplishment of his favourite project, and to put no restrictions to the youth's inclinations. The time of young Taylor was the period of the war, and his gratitude to those who had contributed to the periodicals, and to translations from the best German writers.

When the French revolution had convulsed the Continent of Europe, it extended its influence over no small proportion of the English nation; of this influence the mind of Taylor was adaptable to see the force, and he soon became ambitious to add to his other distinctions that of being prominent in a political character. The quiet of the study was now exchanged for the noisy meetings of political debaters.

Taylor allowed himself to be enrolled as secretary of a democratic club established at Norwich. His political activity however, so far from interfering with his desire to obtain literary distinction, served as a stimulus to bring his writings before the public, and thus to extend his reputation beyond the limits of his school. In his last works he attempts a poetic translation of the "Lenore" of Bürger was the first publication by which he became generally known. This translation, which preceded that of Spencer, still moves on the stage, being still regarded in this country as containing some variations from the original; that of the most importance being the liberty he has taken to transfer the scene of the poem, which in Bürger is towards the end of the Seven Years War, to the time of the Crusades: in this he has been followed by Sir Walter Scott, to whom the public is also indebted for a translation of "Lenore." This work was soon after followed by several other poetic translations from the same source, composed by other English and German poets, by him, also appeared in various magazines and periodicals. Those he afterwards collected together, with explanatory observations, and published in 1830, in three large volumes, under the title, "Survey of German Poetry." The peculiar metre to which he has adapted many of these translations, and a honesty and too familiar style of expression, have exposed him to some severe criticisms.

In the year 1798 he became acquainted with Southey, whose political opinions in early life were similar to his own; an interesting collection of their correspondence will be found in the biography of Taylor, referred to at the end of this article. In his life of him he describes his first interview with Sir James Mackintosh and Dr. Parr; and vividly, though not perhaps impartially, delineates their manner and conversation (l. p. 296).

Southey, who was employed upon the war of the French Revolution, induced Mr. Taylor to retire from the management of his father's business: a circumstance which enabled him to devote all his time to literary pursuits. He was not only a diligent scholar, but a lover of poetry. His Specimens of Specimens of English Poets, 4th ed. 1813, was written to give a complete and correct view of the English literature of the period. His talents as a poet were unequal to the task of producing such a translation as the Wallenstein of Goethe, or the Faust of Lessing, to whom he devoted himself, and yet he is a poet, and that, unless a new or an original spirit is infused by the translator himself, there will remain nothing but a "caput mortuorum." The best translators of poetry therefore have been those who have blended their own original composition. (Tytler's Essay on the Principles of Translation, p. 873.) Those remarks will account for the chief and almost exclusive interest which Taylor takes in the lives and works of past and present English writers, and the Memoir of the Life and Writings of the late William Taylor of Norwich, &c., by T. W. Robertbs, F.G.S., of Norwich, 2 vols. 8vo., London, 1843; Quarterly Review, vol. III., p. 27-68.)

TECO'MA (from Tecomaxochil, the Mexican name of the species), a genus of plants belonging to the natural order Bignoniaceae. It has a campaspe 5-toothed calyx, a short-tubed corolla with a campaspe throat, and a 5-lobed biliate limb, four dasyoomous stamens with a sterile filament of a fifth, a bilamellate stigma, a siliceous-fringed 3-celled capsule having the sepals septum contrary to the valves; the seeds are purple-winged, disposed as the apressed stamens, in the axils of several bracts or scendent plants, with unequally pinnate or digitate simple leaves with terminal pinnules yellow or flesh-coloured flowers. They are natives of the Old and New World in the most tropical and sub-tropical regions. They are all elegant plants and well worthy of cultivation.

T. radicans is a climbing glabrous plant with rough rooting branches, 9 ovate acuminate osceol serrated leaflets, the racemes of flowers from the terminal and axillary leaf axils, the corolla tube of the corolla 5 times longer than the calyx. This is a hardy plant in our climate. It is a native of North and South Carolina, of Florida, and Virginia. This plant has been a great favourite in this country. It thrives on sandy soil, usually throwing out roots from its branches in the same manner as ivy. The flowers grow from the ends of the branches in large
bunches, and the tube of the corolla gradually swells out in the form of a trumpet; hence this and some of the species of Bignonia have been called trumpet-flowers.

*T. stana* is a small tree with somewhat tetragonal glabrous branches; ovate-lanceolate, acuminate serrate and glabrous leaves, the racemes terminal simple. This plant is a native of various parts of South America, the West Indies, and Mexico. The roots of this plant are reputed diuretic.

Several other species of *Tecona* have reputed medicinal virtues. *T. speciosum* is said to be a useful diuretic, also a cathartic. *T. impetiginosa* and *T. Ipex* contain large quantities of tannin, and decoctions of the bark are used by the Brahmans for the treatment of ulcers and a gargoyle in ulcers of the throat. The leaves are milder and are employed in affections of the eyes. In cultivation the species of *Tecona* may be treated in the same general way as recommended for the species of Bignonia. (BIGNONIA, P. C. S.)

**Lindley, Vegetable Kingdom; Don, Gardener's Dictionary.**

TRODAZILLIA (named after Robert Trosdale, author of a catalogue of plants growing about Castle Howard), a genus of plants belonging to the natural order Cruciferae and the sub-order Angustiseptae. It has a roundish notched pod, boat-shaped valves, their backs keeled below, narrowly winged above; the seeds two in each cell; the petals either equal or the two outer ones larger. The species are annual, with short smooth herbs with stalked expanded vertical leaves. The flowerv when white, *T. nudicaulis* is the *T. Beris* of De Candolle. It has unequal petals and numerous leaves spreading on the ground. The stamens have a considerable number within, the pouch emarginated and curved, the arrivals in England, France, Germany, Denmark, and Sweden. It is the only British species.

*T. lepidum* is a native of Europe, particularly of Spain. It differs but little in general characters from the former species; there are two varieties of it.

If the seeds of these little annuals are sown on rockwork or in dry sandy places they will scatter themselves and increase rapidly.

**Don, Gardener's Dictionary; Babington, Manual of British Botany.**

TELEGRAPH, ELECTRIC. The electric telegraph, although it has only begun to attract the attention of the public from a comparatively recent date, has nevertheless not originated in any sudden but happy idea. The possibility of such an application of electrical power had long been imagined; and from the commencement of the present century, the attempts to render one or other of the phenomena of electricity subservient to such a purpose, have been numerous and interesting. In the sequel we have endeavoured to trace briefly the history of the remarkable series of inventions, of which any authentic account exists. We have arranged them as far as possible, in their proper order of succession, down to the present time, and have shewn how the various forms in which it is now presented in England; omitting those subsequent stages of the invention, which have related rather to the improvement of details, than to the adoption of any new principles of connection.

With this subject the Electric Clock is so far interwoven, that we have introduced a short description of its mode of action.

From the earliest date which we can assign to the existence of an electric telegraph, its essential parts have been the same. These are, the source of electrical power; the conducting material by which this power is enabled to travel to the receiving end; and finally, the instant, in the distant end of the line, the existence of this power, its amount, or the direction of its action is made known to the observer. In the earlier stages of the invention, the investigations of its promoters were confined to the latter of these three essentials; and so long as the illustration of the idea was confined to the lecture-table of the philosopher, or to the scientific museum, this part justly claimed an undoubted precedence. Later, the additions to the principle to purposes of general utility, arose the necessity for an equal, nay, almost for a greater degree of attention to the two former requisites. We shall see, in our brief retrospect of the history of this invention, how this fact developed itself.

The experiments of Dr. Watson and others, about the middle of the last century, and the humorous display of electrical phenomena which Franklin mentions as having been exhibited on the banks of the Schuylkill, at the same period, may possibly have suggested some notions of the conveyance of information, by means of electricity. The earliest authenticated instance of any attempt to reduce this idea to practice, appears to have been the experiments of Mr. Faraday, where, however, of the simplest possible construction. He employed, as an indicator, a pair of pit-balls; which were suspended from one end of a insulated wire, and caused to move by the operator taking his station, provided with an electrical machine. On charging the wire with electricity, the pit-balls would exercise mutual repulsion, and diverge from one another; then, by discharging the electric depôts, or by the contact of some conductor, the balls would collapse. It is evident that certain numbers of successive divergences might be made to denote particular preconcerted signals.

To account for this, the inventor intended to apply these indications. Subsequently to this, the phenomenon of the spark was used for the transmission of signals. It is well known that on the passage of electricity through an interrupted conductor, a brilliant spark of light is seen, at all the breaks in the continuity of the conducting material. This fact is well known in its application to various electrical toys in the present day. We allude to the outlines of birds, animals, or stars, which are formed of small pieces of tinfoil, attached to plates or strips of glass, at such distances asunder, that an electrical charge may be readily passed through the whole space. When this is done, the points of the figures are luminous for an instant, and leaps across the small intervals between the successive pieces of tinfoil. Were the various letters of the alphabet formed in this manner, upon a table, and connected each with one of a discrete series of wires, there would be a combination of letters, visible in a darkened room, by passing an electrical charge through the appropriate wire. This in fact constituted the Telegram of Reizter, invented in 1745.

A scheme that simplified the former form of apparatus, involving the same principle, was constructed by arranging the several wires in succession, with a single break in each. The various wires bore the names of the different letters or figures, and any required signal was indicated by passing a spark to the proper wire, when the spark visible at the interruption of the circuit would denote the letter to the observer at the farther end.

This was the point to which the invention had progressed, at the commencement of the present century. The discovery by Volta, of the battery which bears his name, forms the commencement of a new era in electro-telegraphs, although no immediate application of the phenomena of the galvanic current appears to have been made. One or two points present themselves for our consideration, before proceeding to the later periods of our history.

In reference to the extensive adaptability of the electricity derived from the ordinary machine, and that from the Voltaic battery, to the purposes of electric telegraphs, we may add that the progress of wonderful experiments has fast advanced to such a degree that the identity of the force in both machines, we have shown that in operating with the electrical machine or the Voltaic battery, we are dealing with the same powerful agent, only under different forms, homogeneous or Electrical electricity presents with phenomena which indicate its high degree of tension. It possesses the power of passing visibly in the form of a spark, through a greater or less space, when present in small quantity, so that a slight break in the conductor is not sufficient to prevent its passage. The Voltaic current, on the contrary, unless its intensity be elevated to a high degree, is unable thus to leap across more than a very minute interval. The researches of Mr. W. Cooke, a professor of electricity, to the nearest state of insulation, in the wire destined to convey the former, than is requisite in the conductor for the latter. When, therefore, the extension of these conductors over many miles of country is attempted by him, he has endeavored to the readers, that the impediments to the use of the former current were and are almost insuperable, from the difficulty of maintaining through so great a length, the requisite degree of tension, for safety, there would be provided that the uniformity of the conductor be insured and its capacity be sufficient, a much less perfect insulation will suffice. Another point to which it appears desirable to allude here, is the action of the current of electricity in the human body, is a fact well known, that with respect to the Leyden jar, the shock caused by the passage of the electricity through the body is not experienced, until the circuit between the outside and inside coatings of the jar is completed, by touching them both as
once; or by so nearly completing the circuit, that the electricity may leap across the interval in the form of a spark. When we present our knuckle to the conductor of an electrical machine, and take a cork from it, the zone of completion of the circuit is less apparent, though the necessity for it is not less absolute. The body in fact forms the communication between the prime conductor and the earth, from which the circuit is delivered. Platinum inverts the idea of a conductor not in constant supply. It draws its constant supply. To extend this same principle farther, if we conceive two wires extended parallel to one another, to any length, and put a cork at their two ends; a Vitali respectively, no indications of the passage of the electric fluid through either can be found. But if the wires be brought in contact at any point, or if a sufficiently good connection be made to conduct them, and that conducted the circuit, the passage of the fluid from one pole of the battery to the other through the extended wires will take place immediately. If this connection be made at any instant point, by an apparatus fitted for such indications, the direction and amount of the current may be appreciated, as certainly as they could be, were the circuit completed between the battery poles by this apparatus only. To use the words of the late Professor Daniell,* the journeyings of this force must be in a circle, and the arrangements must be made in such a way, that the impulse may return to the point from which it set out; it must circulate. It will be seen how important this is in every exercise upon the construction of the electric telegraph.

We may now return to the point whence we have digressed at so great a length. In 1807, Sömmering at Munich proposed to construct an apparatus of decomposition of water by the voltaic current, as discovered in 1800 by Nicholson and Carlisle. The form of his apparatus was the following:—In a glass trough containing water, thirty-five gold pegs or pins were arranged vertically, this number of pegs corresponding to the letters of the alphabet, together with the nine digits. Each of these pins was connected with a wire, which extended to the place whence the signal was to be transmitted. At each end to the wire a brass strip, arranged in a frame side by side, but like the wires and pins, insulated from each other. Each brass strip bore the name of the letter or figure which belonged to the pin to which it was connected. The operator, when wishing to send any communication, connected the two poles of the battery, with the brass strips bearing the names of the two first letters required. Decomposition of the water in the trough at the distant end, was instantly indicated by the ebulition of bubbles of gas, from the two gold pins thus rendered the two electrodes or poles of the battery. The letters forming any communication were to be in this manner denoted in pairs of letters. If the letters be considered as the quantities of the two gases evolved, to point out the relative position of the letters in each pair. The hydrogen which made its escape in the largest quantity was always employed to indicate the upper letter of the pair. The operator then, if he would bear this rule in view in making his connection with the battery.

In 1815, Mr. Ronalds* of Ramhurst, invented an electric telegraph, in which he rendered the electric fluid the vehicle of intelligence. This telegraph, which was shown to several scientific men, at the date above given, was fully described by the inventor, in a work published by him in 1823. Mr. Ronalds employed the divergence and collapse of a pair of pith-balls, as the telegraphic indication, in which respect the principle was the same as that adopted by Mr. Lomond; but to this simple apparatus, a distinct contrivance was appended, which would render the electric fluid more rapid and easy. A single wire perfectly insulated by being suspended from alken strings, or buried in glass tubes, surrounded by pitch, and protected by wooden troughs, was extended between the two stations. From the end of this wire were suspended in front of the dial of a clock a pair of pith-balls, so that while the wire was charged the balls would remain divergent, but would instantly collapse, when the wire by contact with the earth, or with the hand of the operator, was discharged. A person at one end, having therefore an electrical machine, by which he could maintain the wire in an electrified state, and the pith-balls at the farther extremity, consequently in a state of repulsion, would at the instant of this operation see the instantaneous indication to an observer at that farther extremity by touching the wire with his hand, which, discharging the electricity, would allow the balls to collapse for an instant. But instead of merely employing the successive movements of the pith-balls to denote the various signals, Mr. Ronalds added another apparatus for this purpose. Two clocks, very accurately adjusted to the same rate of going, carried, instead of the ordinary seconds hand, light discs, on which the various letters of the alphabet, the figures, and other required signals were engraved. These discs turned with a regular step; through a screen of metal, in which was made a small opening, in order to view the part of the disc where the signal was being seen. As the discs turned round, each letter in succession would be visible through this space; and it is evident that if the clock indicated by the same signal visible, the movement of the discs would be of a regular view at the same time. One of these instruments was situated at each end of the communicating wire. The operator who was about to transmit, once having watched the dial of his clock until the letter he required was visible, and at that instant discharged the wire. The momentary collapse of the balls at the distant end would then warn the observer to note the letter visible on his instrument, which would form part of the intelligence to be received. The successive letters or signals constituting any message were denoted in this manner as the clock dials continued to turn round. In order to avoid the necessity for constant attention on the part of the observer, an arrangement was adopted by which a pistol could be fired by the spark at the further end, to summon the attendant to his instrument. Various signals were also connected beforehand with the use of different kinds of wire for the transmission of any intelligence was lessened. These experiments of Mr. Ronalds were made with the intervention of several miles of wire, carried backward and forward across the lawn of his house, and were so managed and operated as to satisfy the attention of the most fastidious inquired by them. But before we proceed to come to the construction and action of the Dry Pile or column of Mr. Ronalds, it may be specified that it consists of many hundreds, or even thousands, of small discs of silver and zinc foil, piled up in regular order, with the intervention of writing-paper discs between the succeeding pairs. They are then usually enclosed in a glass tube, and pressed firmly together, by means of screw-caps or ends of the tubes. The ordinary length of a cylinder of electrical fluid is sufficient to excite weak voltaic effects in the pile, which are manifested by the two ends exhibiting constantly opposite electrical states. The bob of the pendulum in Buzengeiger's discovery, which he used to indicate the presence of electrical charge; in consequence of which it was repelled by this boll, and attracted by the other. These actions, though very feeble, are long continued, and might suffice to maintain a movement of a very light globe, as the opticn's windows at the present day, slender frames are often seen revolving, with paper figures of chariots and horses, under the influence of two or more of these Dry Piles. In 1819, Professor Gersted of Copenhagen made his great discovery of the action of the galvanic current upon a magnetic needle. He observed that when a galvanic current is passed along a wire, placed parallel and near to a magnetic needle, free to turn on its centre, the needle is deflected to one side or the other, according to the direction in which the current is transmitted. He further noticed that the position of the wire, whether above or below the needle, had an equal influence with the direction of the current in determining the side to which the deflection took place. The power of a single wire in causing this deviation of a needle is very small, but within a short time after Volta's discovery, Professor Schweigger invented the multiplier, as he called it, in which the needle, being surrounded with many successive coils of insulated wire, is acted upon by the joint force of all. This instrument is commonly known in England as the Galvanometer, wherein the deflection has been of the most signal importance. Thus, in 1818, M. Ramd son, at Munich, and M. Brevard at Verona, had each constructed an Electric machine, which received motion from a Dry Pile. 

* Ronalds' Description of an Electric Telegraph, ex., p. 49. Translated from the BntisheiJodn-Mazar, September 25, 1818. In the same work (page 97) Mr. Ronalds, opining the option of Joseph, mentions that the profits of the invention were divided between Mr. Ronalds at Munich, and M. Brevard at Verona, who had each constructed an Electric clock, which received motion from a Dry Pile. 

** Mr. Ronalds, in his work on electricity, published in 1828, informs us that an electric clock was constructed in 1815 by Buzengeiger. A very light pendulum was suspended, with its bob or weight midway between two brass balls, forming the extreme ends of a De Loc's Pile. Having once been set in motion, the pendulum would continue to oscillate between the balls, receiving at the end of each vibration a shock or impulse, from the attraction of the balls, which it had just touched. The upper end of the pendulum was made to cause the revolution of a small ratchet wheel, by means of the alternate action of two catches, or pellae, one on either side of the wheel. To many of our readers the construction and action of the Dry Pile or column of De Loc may be familiar. It may not however be amiss to add, that it consists of many hundreds, or even thousands, of small discs of silver and zinc foil, piled up in regular order, with the intervention of writing-paper discs between the succeeding pairs. They are then usually enclosed in a glass tube, and pressed firmly together, by means of screw-caps or ends of the tubes. The ordinary length of a cylinder of electrical fluid is sufficient to excite weak voltaic effects in the pile, which are manifested by the two ends exhibiting constantly opposite electrical states. The bob of the pendulum in Buzengeiger's discovery, which he used to indicate the presence of electrical charge; in consequence of which it was repelled by this boll, and attracted by the other. These actions, though very feeble, are long continued, and might suffice to maintain a movement of a very light globe, as the opticn's windows at the present day, slender frames are often seen revolving, with paper figures of chariots and horses, under the influence of two or more of these Dry Piles.
enables him by its extreme delicacy not merely to discover the existence of feeble currents, but also to measure their force and direction with extreme accuracy. Under a strong current, this discovery for the first time reveals the hostility of the Electric Telegraph, which has spread so extensively over England.

Very shortly after this important discovery had been made, Oersted, Arago, Davy, and others, succeeded in rendering iron magnetic, by the passage of a galvanic current through a wire coiled around the iron. It was found that, provided the iron could be magnetised perfectly soft, the magnets so produced lost their magnetic properties during the actual transmission of the electricity, and was lost immediately on the interruption of the electric circuit. If the iron which was exposed to the influence of the galvanic current was composed with carbon, its magnetic power became to a greater or less extent permanent in it. These two principles have, since their discovery, formed the groundwork almost all the electric telegraphs which have been proposed, and certainly of all which have hitherto been found practicable. Far be it from us, however, to assume that these principles must hereafter bound the indefinite growth of men of science, or that no further progress can be made. Much has already been done, but far more, as yet latent and unknown, may be before us.

M. Ampère suggested the employment of the discovery of Oersted in 1830, and this suggestion was accepted by Professor Ritchie, in a model telegraph exhibited by him at the Royal Institution. M. Ampère’s plan however was far from possessing the simplicity, so essential in an instrument for so extensive a purpose. Not less than thirty pairs of conducting wires were necessary, according to his scheme, for maintaining a Telegraphic communication. M. Schilling also in 1832, following the idea originated by M. Ampère, proposed a similar form of telegraph, in which there were as many of these galvanometers, each with its appropriate circuit, as there were letters or signs to be used in the various communications. The momentary deflection of any one of these needles, by the completion or breaking of the galvanic circuit with its wires, denoted the required letter or sign. The same plan, to a certain extent, seems to have been followed by M. Alexander, in his telegraph, described about the end of the year 1837. In this instrument a distinct needle was employed for the indication of each letter, as in M. Schilling’s apparatus, these needles bearing at one end light screens of paper, which concealed from view a letter or figure, until by the deflection of the needle the screen was removed, and the letter brought into sight. M. Alexander however effected one great improvement, in substituting a single return wire, to which one end of all the coils was joined for the several distinct return wires existing in the previous invention of M. Schilling. At a later period this latter gentleman undertook a series of experiments, with a view to the establishment of a communication by means of a single wire; but some mechanical difficulties appear to have been experienced, and consequently the experiment was given up before the death, which occurred while he was engaged in the prosecution of his investigations. In both of these telegraphs all that was requisite, in addition to the indicating apparatus and conducting wire, was a battery of accumulators, by means of which batteries could be made with any pair of wires in the former, and with any single wire and the return-conductor in the latter of the two inventions. In M. Alexander’s instrument, a set of keys resembling those of a pianoforte, and corresponding to the number of needles, were arranged on a frame or table. One pole of the battery being connected to the return or common wire, the other wire was joined to a plate of metal, or to the trough of mercury, extending beneath all the keys. On depressing any key, the wire belonging to it, which was continued to the end over the battery connection, was brought into contact with the trough. The current would then flow along the conducting wire, around the multiplier-cord in the distant instrument, and return by the common wire to the voltaic battery. The keys bore the same letters as the needles to which they were connected, so that the operator communicated any letter by pressing down the corresponding key.

In these two instruments no use was made of the power which exists, of determining the deflection of the needle, by the aid of which the operator of a telegraph can find the exact points of the circuit at the other end where the current is applied.

In a telegraph as advanced as the invention of M.M. Gosselin and Weber, the varied deflections of a single needle appear to have formed the code of signals. From the use of a single telegraphic needle, however, so remote a point as the different signals, it is to be inferred that the indications wanted precision and distinctness.

In June, 1837, the experiments of Meeks, Cooke and Wheatstone, which were begun for preening for more than a twelvemonth, appeared so far successful as to induce them to apply for a patent for their inventions. The principal points of novelty in this patent were the use of a much smaller number of needles, together with the employment of the temporary magnetism excited by the current in soft iron, to ring an alarm, either directly or indirectly, by the means of suitable machinery; and the reciprocal arrangement by which the invention was rendered practically applicable to a long line of communication. The telegraphic instrument shown in the drawings annexed to their specification, and which was brought into use on the Great Western Railway shortly after the date of the patent, consisted of needles, arranged with their axes in a horizontal line. The needles when at rest hung vertically, by reason of a slight preponderance given to their lower ends. Each coil was connected with the respective pole of the battery to its distant instrument, while the leads of a second wire being brought into contact with the other pole, the current returned by the rod of metal connecting the coils and the second wire to the battery again. Two needles were placed in each of these magnets, so that the current would pass in opposite directions around their coils, and consequently that the deflections must be in contrary directions. The needles would therefore converge, either above or below their line of centres, as one or other of the pair of keys belonging to each wire was depressed. Fixed stops were so placed on each side of the needles as to limit their motion, and when resting against them, the needles were parallel to two converging lines, at the point of intersection of which, a letter was placed. This was the signal indicated by the movement of the needles. In a similar manner, as lines were drawn diverging from the centre of each axis, mutually converging, another pair of needles was placed at the point of intersection, at each of which was a letter or signal. Any of these letters could be indicated by the simultaneous movement of two needles, so that a communication might be rendered between the opposite ends of the line. The sending of one signal at the same time a plan was recognised, by which the number of wires requisite for maintaining a communication might be reduced, by using one of them as a return wire only, where before there would have been required a pair of wires. Thus, a needle could by the use of this wire be deflected by itself either to the right or left, and thus of course each would furnish two signals, in addition to those formed by its simultaneous deflection with any other. The instruments at the two stations were always rendered reciprocating; that is, at each

*Tesla's Lectures on Heat and Electricity, p. 912.

† In this and other parts of this article, where, according to the transmission of the telegraphic currents through a conductor, it is necessary, in order to simplify the description of the electric telegraph, to describe the connecting arm from one end of the pole of the battery, and, returning after its circuit to the other. Theory however, we are not prepared for the position of the element as it appears to have been developed at once at both ends of the battery, than to any power acting in one direction only.

* It appears desirable here to add a few words explanatory of the actual origin of the Electric Telegraph. Mr. Cooke at first had his attention directed to the subject in consequence of some experiments of Professor Wheatstone, in which he had the good fortune to witness. Thoroughly impressed with the possibility of the oft-attempted scheme of employing Electricity in the conveyance of information, the inventor was seized with the idea of its application to telegraphic purposes. In the early part of 1837, after having been engaged nearly a twelvemonth in the construction of various Telegraphic instruments, and in efforts to bring them into use on some of our Northern Railways, Mr. Cooke became acquainted with the experiments of Professor Wheatstone, whose experiments were directed to the same subject, and whose experiments and researches in electricity were in the highest degree correct and important. The public attention was also given by the joint names of those two gentlemen, as several which succeeded at extreme intervals. The relative connections of Mr. Cooke and Professor Wheatstone, with this invention, to the success of which both have contributed, are expressed in the following passage with which this note may be appropriately concluded:—While Mr. Cooke is happy to be enabled to acknowledge the assistance he had the honour of receiving from Professor Wheatstone, in this part of his invention, to the success of which both have contributed, he cannot forbear expressing his acknowledgments to the many others whose assistance he has received in having practically introduced and carried out the Electric Telegraph, as a useful undertaking, and Professor Wheatstone is acknowledged as the scientific patron, whose name will ever be prominently connected, as having first led to it, and to the manufacture of it, as an instrument of utility and science which would attract the rapid progress which this important invention has made in so short a time were associated.
end of the line were placed an instrument, a set of finger-keys, and a voltaic battery, so that either station could transmit or receive a signal. By a beautiful arrangement, the keys, on being released after depression, were made to resound by chemicals, over the line in tremors which had been the signalling station to become the recipient. By this means messages and answers, or words and their acknowledgments, could follow one another without the necessity for any intervention or announcement of position.

The bell or alarm which was to be rung, when the attention of the clerk at the distant terminal was required, was either direct or indirect in its action. In the first case the bell was a fine iron bar, arranged in a line, which had been rendered temporarily magnetic by the galvanic current, and was made to attract an armature, likewise of soft iron, towards it, and by this action kept a small hammer against a bell. In the second form of alarm, the movement of the armature merely released a detent or catch from a train of clock-work driven by a spring or weight. This clock-work, by the intervention of a scape-wheel and pallets, rang the bell in the manner well known in common alarms.

In the early part of 1835 Mr. Cooke obtained a patent for some further improvements of this apparatus. Of these the most prominent was the mode of introducing of the intermediate apparatus. Before the date of these patents, the two stations at the extremities of a line of telegraph had alone been put in communication with each other; but Mr. Cooke devised means by which any intermediate point might be introduced between the two terminals, and all intelligence rendered simultaneously visible in all or in any of them, as required. Furthermore any one of these instruments could be used for conveying a single相比于 drive, or ribbon, or any other part only; and by an admirable contrivance, the same mechanical adjustment which limited the connection of any intermediate instrument to one part of the line, placed its bell in the circuit of the other part. Thus if, while intelligence was being transmitted in one direction from an intermediate station, some message of importance were required to be sent from the terminal, or any other station on the extended side, the ringing of the bell at the originating station would warn the attendant to restore his instrument to its intermediate position, and thus leave the line clear throughout.

In the same patent were included some important improvements on the mode of protecting and isolating the wires, which were to be laid beneath the earth, in tubors or troughs of wood, iron, earthenware, or other materials; and also in the expedients for detecting the exact position of any accident or derangement, without the necessity of uncovering the whole length. Two needles were also shown to be sufficient for carrying on a complete communication with ease and rapidity.

In the course of the ensuing year (1836) Messrs. Cooke and Wheatstone obtained a patent for their telegraphic apparatus, which were first put into operation upon the Great Western Railway, where its capabilities were tested severely. The result of this trial were most gratifying to the inventors, and demonstrated that the undertaking, yr...
The telegraph erected by Prof. Morse, in 1844, between Baltimore and Washington, a different mode of recording the signals was adopted. The use of the pencil was found objectionable, from its so frequently requiring fresh pointing, and from its lightness. The same arrangements were retained in regard to the paper, but it was made in its course to pass under a roller having a groove around it. The long arm of the lever carried a blunt steel point, standing out from its side; and another arm, vertically under the first, rotated in a vertical axis, with the same side against the paper. When therefore the arm of the lever was elevated, by the attraction of the magnet upon the armature, the steel point pressed the paper into the groove, and produced an indentation. If the attraction were momentary, a second point, as produced; but if the action were continued for a longer time, a lengthened depression was the result, as the paper was drawn on. The combinations of these two kinds of marks denoted the various letters and figures.

In his first instrument, Mr. Morse produced the requisite groups of angles by means of type having as many projecting ridges or teeth as there were to be angles. These being arranged in a frame, as required for the message, made the successive contacts with the battery as they were drawn under a lever or spring. Subsequently however a single key was used, by depressing which with the finger the first needle might be raised; the first necessary plan had the advantage of requiring no exertion of memory on the part of the operator, after the message had been set up properly; but nevertheless in practice, the second, in which all depended on the second selection of the person transmitting any signal, was preferred.

In the year 1837 Mr. Davy of London obtained a patent for an electric telegraph. The actual principles of his invention were three: first, the employment with each wire (of which there were to be used) of two magnetic needles, each movable in one direction, but stopped in the other, in a manner analogous to that in Steinheil's telegraph; secondly, the use of a supplementary battery, to effect the registration of the signals, the connection of this second battery being made by the deflections of the needles; thirdly, the method of registering or recording the various communications, by causing the current of the supplementary battery to pass through a ribbon steered in a solution of iodide of potassium and starch. The salt being decomposed by the current, a blue spot was produced by the combination of the iodine with the starch, and the position of one or more of these spots across the breadth of the ribbon, determined the nature of the signal transmitted. The action of the two needles in each circuit was analogous to that of the needle and fixed stops in Dr. Steinheil's telegraph, in respect to their alternate deflections, according to the direction of the current. Instead however of carrying a cup for ink, each needle bore a small metallic arm on its axis, which needle was deflected, by moving the fixed stop, came in contact with a brass pin or stud, and thus completed the circuit of the supplementary or registering battery. The stud belonging to each needle was connected with one of a series of pistons, the whole of which, in their respective movements, were connected at equal distances around a light drum. The edges of these rings being lightly upon the prepared ribbon, as it passed over a metallic cylinder driven by a weight and cord. Instead however of allowing the ribbon to move at a uniform speed wholly independent of the rate of signaling, Davy ingeniously connected the two parts of the apparatus together, by such means that the transmission of each signal caused the revolution of the cylinder bearing the ribbon through a small space; so that the successive registrations forming any communication were placed at regular intervals apart upon the fabric. This was done by introducing a small electric circuit into the circuit of the registering battery, so that whenever this circuit was completed an armature was attracted, and one tooth or division of the cylinder released from a catch or pallet. The ribbon itself was divided into spaces by knives placed on the cylinder. The metallic cylinder was turned, and the edge of each platinum ring pressed upon the fabric, in the centre between two longitudinal lines, while the space through which the cylinder turned, at each release, corresponded to one tooth of the cylinder or one division of the small spaces, were brought in turn under each ring, as the ribbon passed onwards, receiving the registrations as it moved. If we now suppose one of the supplementary battery to be connected with a metallic cylinder bearing the needle, and the other with the axes of all the magnetic needles, the action of the apparatus will be readily rendered apparent. When a current was transmitted from the communicating station, so as to cause the deflection of the first needle of a pair, the second needle of the same wire being pressed against its stop and fixed), the arm of this needle coming in contact with the brass pin or stud, would complete the supplementary circuit. Thus, as the needle was deflected by the current, the pole of the metallic cylinder would be attracted, and consequently the edge of the platinum ring would be turned, and so on with the others. After each signal the ribbon would be advanced one division, so that the successive registrations would take place in succeeding transverse divisions of the fabric. The person who is to communicate has a apparatus, in which, by depressing different keys, he can transmit the electricity in one or other direction through any wire, making it return either by a spare wire or by ground, or be employed another of the signalling wires to return the current. In the first case, he would produce a single spot on the ribbon from one ring only; while in the second, spots from two or more rings would occur. The principle is to multiply the various simple and combined indications, a sufficient number of variations to express the necessary letters and signs could be obtained.

In the year 1840 Professor Wheatstone patented his electro-magnetic telegraph, in which the indicating power was the magnetization of soft iron by the electric current. The object of the invention was to produce, by excitation and demagnetization of the magnetic needle, places of soft iron, certain determinate and definite movements of rotation, in dials or indicators; by which movements signals might be given, of various kinds and in various modes. The first part of the apparatus which maintains the latter state of the iron, is a thin disc of wood, turning horizontally upon a pillar or axis, has its circumference divided into equal spaces, alternately filled up with metal or ivory. The metal divisions communicate with the central column, and through it with one pole of a battery, of which the other pole is connected with the return wire or with the earth. Against the circumference of the disc rests a spring, from the foot of which proceeds a wire going to the line or long conductor. As the disc is revolved on its centre, the spring rests alternately on metal and ivory, and were there no break in the circuit at the distant station, the current from the battery would be transmitted or intercepted. The second part of the apparatus is produced by a letter or figure, so that by bringing one letter after the other opposite to a stop fixed near the disc, the galvanic circuit would be opened and completed alternately with each succeeding letter, so as to produce by the movements of the roll with spokes or arms radiating around its upper surface; the telegraph which is operated upon by this Communicator, possesses great simplicity both in its principle and construction. One of the spokes is provided at equal distances with a voltaic magnet is placed a small armature of soft iron. When the iron is rendered magnetic the armature is attracted to it, but on interrupting the galvanic circuit the remanent magnetism of the iron causes, and a small reatting spring throws the armature back to its original position. The magnetism thus being inverted, an armature is attracted to it, but on interrupting the galvanic circuit the remanent magnetism of the iron causes, and a small reatting spring throws the armature back to its original position. The armature itself turns on an axis, which carries a pair of pallets, taking into the teeth of an escavement-wheel. In the instrument first constructed accorded with the requirements of the attraction and release of the armature actually formed the motive power of the machinery, the two pallets alternately moving the escavement-wheel onward, one tooth at a time. For this arrangement another was afterward substituted, in which a common spring barrel and fuse were employed to turn the escavement-wheel, and the pallets, actuated as above, merely controlled its revolutions like the same parts in a common escapement. In this case the object was the same, that of communicating to a light paper or micro dial, bearing letters around its circumference, a step by step motion, wholly under the control of the operator at a distant station; so that he might be able to transmit letters or telegraphic signs, in a manner as in a screen, through which it would be visible to an observer. The number and order of the signals upon the paper disc corresponded with those on the Communicator previously described. Supposing for instance that the letter A were
opposite to the fixed stop in the Communicato, and that the same letter was visible through the opening in the screen of the tape; if the telegraph was then removed, the Communicator rested on an ivory division of its circumference, no current would then flow from the battery. But if the Communicator was then removed to the fixed stop, the spring would rest on a brass division of the circumference, and the current would flow freely through the circuit and the coil of the electro-magnet. The armature being then excited to a uniform motion to the point corresponding to a line on the escape-wheels, and the following signal B would appear through the opening in the screen. The movement to C on the Communicator, breaking the circuit, would release the armature, and cause it to swing on the escape-wheel with the same velocity as before; and would let go, bringing round C also on the telegraph. In this manner by turning the Communicator round steadily with the finger, until any required letter came opposite to the fixed mark or stop, the same letter could be brought into view on the telegraph dial. A momentary pause would then be made, before continuing the movement to another signal, so as to enable the observer to note each letter in succession as it appeared. The same plan was obviously applicable to causing the rotation of a hand or index around a fixed dial, so as to point to any required letters or signals, one after the other. It is indeed unimportant whether a dial be made to move or lose its screen having an opening in it, or, the dial being fixed, a hand travel round so as to indicate any requisite letters upon it. In this, as in the needle instrument, the communicating stations would have a mutual and reciprocal action from the same source, and another arrangement another very marked advantage arises. The operator sees upon his own dial or instrument the signals which he makes upon his correspondent's apparatus; so that he is once aware of any accidental errors in signalling, and is prepared to rectify it forthwith. Still further to reduce the chance of an error, each word as it is completed is acknowledged by the recipient by a single preconcerted signal, before the next word is commenced. This telegraph requires only a single wire for its use, the return of the current being provided by the earth.

The essential principle forming the basis of this invention presented themselves to Professor Wheatstone. Of these we will describe two of the most prominent. It is evident that if the operator were to move the communicating part of the apparatus, step by step, in accordance with the beats of a clock pendulum, a hand upon the telegraph at the distant station would rotate exactly as if attached to the clock, and show precisely the same time. But that the clock itself might be made to do this same duty, and thus telegraph its own time to any number of distant stations, was an idea which did not long fail to occur to the inventor. This was effected simply by attaching a small common pendulum to the axis of the telegraph clock; a spring being placed so as to make and break the circuit, as the divisions of the disc passed under it. These electric clocks were either constructed so as to derive the motive power from the action of the arms, or in the form of electro-magnetic telegraph first alluded to; or the movements of the armatures were employed only to control the power of an ordinary spring or weight. It is evident that any number of secondary ‘telegraph clocks’ might thus, if connected by a single wire, receive their motion from one governing chronometer at a central point. In addition of Professor Wheatstone's a form for regulating all the clocks of the metropolis, by means of wires passing under the streets, and connecting the subordinate instruments with one central chronometer, an eminent artist aptly remarked, that ‘he proposed to lay on Time through the streets of London, as we now lay on water.’

The second application above mentioned to which Professor Wheatstone turned his attention, immediately after having completed the details of the electro-magnetic telegraph, is that of enabling the machine to print its intelligence, instead of rendering it visibly, or to do both at the same time. To effect this it was only necessary to replace the necessary portion of the light metallic disc, cut in radiating lines so as to form a circle of delicate springs. On each of these, instead of a visible character only, was placed a small type. The type-disc was then made to rotate, precisely as the model uniform move of the machine, carrying a sheet of paper covered with white paper; there being interposed between the type and the cylinder, a sheet of the copying or transfer paper well known as the Carbonic ink paper. Any requisite

type could therefore, by the same action which brought the various letters into view in the signal telegraph, be placed in the proper position on a sheet of paper, as in the case of the printing telegraph. The tube of the cylinder. Immediately that any one was so placed, a small hammer, acting by a train of wheel-work precisely similar to the striking train in a clock, struck the end of the type, and by means of the impulses of blow, pressed the letter on the cylinder. The succeeding signals were similarly impressed, one after the other. The train giving forward motion to the paper, the letters would pass in succession over the armature which moved the type-disc; and by an arrange-ment sufficiently obvious, this train was made, after each impres-sion of a letter, to move the paper cylinder round through the same distance as before. This cylinder did not turn on a simple axis, but on a screw so that the words of any communication were arranged in spiral lines around it. When the paper was unworked, to be placed by a fresh piece, the message would be found printed in slightly sloping lines from one side to the other. The action of this instrument was very perfect, and it appeared to possess every requisite which could be demanded in a registering telegraph. There were however some very obvious impediments to its being brought into use, in the increased cost of the apparatus, and the slowness with which signals would be rendered, as compared with the needle instrument.

Towards the end of 1840 Mr. Bain, in conjunction with Mr. Barwise, patented a clock which was to be set in motion by electricity. It was proposed by the inventors to employ the electro-magnetic circuit to turn the pendulum of a clock, at the end of its oscillations, in the following manner:—An electro-magnetic coil formed the base of the pendulum, having its ends so placed as to come very near to the ends of two permanent magnets, when at the two extreme points of its swing. On reaching these points, the pendulum itself, by coming in contact with a slender spring, completed the circuit of the galvanic current through the coil, in such a way that the end of the coil then nearest to the magnet on the side to which the pendulum had oscillated, was momentarily ended with the same polar force as the magnets themselves. The result was a renewal of the current in the coil and magnet, and the former, being free to move, receded from the latter with a small impulse, sufficient to carry the pendulum to the opposite end of its oscillation. The same effects then took place, in respect to the other fixed magnet at that side. A small force was thus communicated to the bob of the pendulum, at each extremity of its arc, which was sufficient to maintain its vibrations undiminished; and at the same time to put in motion, by means of the ordinary arrangement of a scape-wheel and pallets, the works of the clock acting upon the minute and hour hands. By causing the circuit to be completed by the primary merely through the galvanic current, a return through the similar coils of other instruments at distant stations, connected by appropriate wires, a series of such clocks might be made to work together with absolute accuracy.

In July, 1841, Mr. Bain exhibited at the Polytechnic Institution in London an electric printing telegraph, and in the following year he proceeded to patent an improved form of the apparatus. The essential principles of this contrivance are two.

First, the employment of type, mounted on the periphery of a disc or wheel, capable of revolving with its edge carrying the type very near to a cylinder covered with white paper, between which and the type-wheel a piece of transferring paper or ribbon was placed. The cylinder had a small movement in a spiral direction communicated to it, after each impression of a signal. The action of this part of the apparatus will be readily understood, from the brief description of the printing telegraph of Professor Wheatstone, already given. It is only necessary to particularize, that in Mr. Bain's machine the type were arranged on the edge of the disc or wheel, radiating from its centre; and that the printing of any one upon the cylinder was effected by the movement forward of the entire type-wheel and its axis, by a crank and connecting gear in the printing train. This head of the machine would be struck down by the printing-hammer, in impressing a signal.

The second principle is that of the use of two clocks at the two communicating stations, to rotate the type-wheels with uniform motion, both cylinders revolving exactly at the same rate, and being started from the same signal, would bring continually, at each station, similar type opposite to the paper cylinders at the same moment. The
action of this part of the apparatus is exactly analogous to that of Mr. Ronalds, already described. A hand or index revolving on a dial in front of the machine, at the same rate as the type-wheel, indicates to the operator the signals which are constantly being traced on a cylinder, which was secretly defended in his own instrument, and therefore, if the clocks go accurately together, in a similar position in his correspondent's instrument.

At the same time this hand, by coming in contact in its revolution with a pin, placed by the operator opposite to any signal that he wishes printed, completes the electric circuit at this moment, and by so doing stops the type-wheel, and thus prevents its printing the signal behind it. A similar signal, having thus been impressed on the cylinder at the two ends of the line, the operator removes the pin, and replaces it opposite the next signal he requires to send. The moment the pin is removed, and the circuit therefore broken, the hands and type-wheels at each station resume their revolutions, which are again checked by the contact of the hand and pin as before.

Mr. Bain's single-index telegraph, which was the instrument proposed by him for practical use, consisted of two hollow cylindrical coils of wire, placed horizontally a short distance apart, with their axes in the same line. Between them a small bar magnet was fixed across a delicate spring, which in front passed through the dial-plate of the instrument, and was turned up to form an index. The two coils were connected, so that an electric current entering from the line wire would pass through both, and in the case, the bar magnet would be attracted towards one coil, while at the same time it would be repelled by the other. These actions tended to carry the magnet to the same side, as far as the spring to which it was attached allowed it to move. Thus the circuit would be broken, or reversed, by the current inverted the effects of the coils, and the magnet would then pass to the other side.

The combinations of these two movements represented the various letters and words, being denoted by the observer by the index on the dial of the instrument. The movement of the index to the left denoting the letter I, and to the right the letter V, this instrument obtained the name of 'I and V Telegraph'.

In the autumn of the following year (1842) Mr. Bain patented his proposed plan for working an electric telegraph without any galvanic battery whatsoever, or, more correctly speaking, with a peculiar form of battery. At one end of the line he buried in moist earth a large plate of zinc, and at the other end a plate of copper, iron, or other substance such as coke or charcoal, which might act the part of a negative plate to the zinc. Then on connecting these distant plates with a wire insulated from the earth, a current of electricity would constantly pass from the one plate to the other. Indeed the current might be presumed to conduct with a rapidity superior to that obtained with a similar instrument connected with a battery, as above described, may be regarded merely as a battery of one pair of plates, separated by a very wide interval of exciting material, represented by the earth. It was at first supposed by Mr. Bain that this instrument would be applicable to telegraphic purposes, but subsequent experiments showed that it was available only for a few miles of distance; its intensity being insufficient to enable it to travel through any great length of wire. The same reason applied to the magnetism, the intensity of which in this case was expected to be fonder, requiring the earth battery would become very useful and important. In the original part of the year 1843, Mr. Cooke specified his patent for what has been probably the most important part of the invention, regarded in a commercial point of view. This was in reference to the mode of extending the wires between distant stations, so that their insulation from one another, and from the earth, might be maintained by being current, and unavoidable difficulty hitherto incurred. Before this period, the wires having been covered with cotton and insulated by coating them with shell-lac, resin, or pitch, had been laid down in tubes or pipes of wood or iron. This method had been adopted on the Blackwall line, in 1840, and has not since been altered. On the Great Western Railway it was superseded by the new and improved mode of insulation. Mr. Cooke now proposed to insulate the wires by suspending them in the air upon posts or standards of wood or iron; the wires not coming in actual contact with any part of the supporting standard. The insulation was mainly of porcelain wires, and earthwire. The standards were usually fixed at from forty to sixty yards asunder, and at each quarter of a mile a stouter post was placed, to bear the winding or straining apparatus.

This was a simple winding-reel, connected with a machine-wheel and click to prevent its recoil, after the wire had been strained up by its means. The intermediate posts within each quarter of a mile only supported the wire, without reference to winding or straining, but merely to keep it steady. Instead of the copper wires hitherto employed, iron wires of a larger size were now used: By the adoption of this method of extending the conducting wires, the cost of construction of an electric telegraph was reduced nearly one-half. At the same time the risk of imperfect insulation was diminished.

So long as the wires were buried in tubes beneath the ground, it was impossible to prevent their being in any way exposed. But when the tubes were removed from the earth, and placed in the open air, they were more liable to receive injuries, for they could be damaged by being run over by carts, or in various other ways.

But while the tubes were in use, it was necessary to supply at almost each quarter of a mile along the line, a proving or testing post, where the commanding officer could then be sent to afford the means of examining any of them as to their insulation and conducting power. For this purpose Mr. Cooke had invented an instrument called the 'Detector', by which the electric current obtained from the apparatus, or every error or fault discovered with considerable accuracy.

Still with all these appliances, the detection and repair of any derangement of the wires demanded considerable skill, and left the operator exposed to danger at any point; but when the wires were far in sight, and any fault or iatrogen to be discovered, and was easily and quickly repaired. But having traced the invention through a few of its most remarkable stages, up to the time when it assumed the form it at present retains in England, we may add a few words on the mode of applying it to the purposes of a railway. Mr. Cooke's first plan was one of admirable completeness in all its details. We can do little more than indicate its outline, as the full description would occupy far too much space. He proposed to divide the entire line of a railway, if necessary, into portions including each from four to six stations, and to make the traffic and communications within each of these divisions wholly independent of those on any other portion. The stations where these partitions occurred were termed Division Stations, and might be regarded as junctions, or points of junction, of the various portions of the line. At the same time a general system of telegraph connected all the divisions with each other, and with the actual terminus of the line, so as to bind the whole of the railway together into one large system of telegraph, and correspondence between the most distant points. Each station possessed a wire of its own, extending from one to the other terminus of its division, and including at every station a battery of two or more needles; a current of any number of signals by any wire and system of needles, was provided at each point, so that the most ample means of correspondence was secured between all the stations. Each needle was used to denote the condition of that part of the line which was under the control of its own station; and by its means the movements of all trains upon this portion of the railway were made known to the other stations in the same division. All the movements were made by a needle visible by the corresponding needle at all the stations, and as all information respecting the arrival or departure of trains, state of the line, accidents, and impediments, were immediately conveyed from stations to stations by this means, the telegraph, the station master at any point had only to turn to his instrument, to perceive at a glance the existence of any circumstance which might influence the working of the railway. The working of the railway was left to the agents of the line to decide.

Although the plan of executing the conducting wires in tubes beneath the ground, when put in practice on a large scale, presents many difficulties, it is generally held that the introduction of such a system of telegraph will be attended with very great advantage, and will render unnecessary some improvements in the method of insulating and protecting the wires, it is thought it is not so easy to produce a general commercial system throughout England.

It is to be understood that the statements we have made are to include the whole of our previous experiments with each battery see 'Electrical Magazine', pp. 277, 287.
be assumed or inferred, all was evident and visible, and in fact, in the words of Mr. Cook, the clerk at every station possessed in his telegraph a constant bird's-eye-view of the whole of his division. In addition to these 'line' wires, as they may be termed, there were also small wires extended throughout the line, with instruments at each station, so as to afford the means of verbal communication, whenever this might be necessary. The result of such a complete system could hardly fail to be most beneficial, and experience has now proved, that not only accurately and justly all Mr. Cook's measures were planned beforehand.

* The Blackwall has absolutely depended upon this instantaneous means of communication, not only for its safety, but for the very possibility of its being worked. On this railway, however, the telegraphio system is different, i.e., as much as its peculiar locomotive plan, the stations do not require any communication between themselves, but only with the two terminals.

Even on railways possessing a double line of rails, so complete a means of information as that described in reference to the Yarmouth and Norwich line, would tend much to the prevention of accidents and increased safety of travelling. To prove this it is hardly necessary to recall to mind the disasters which have occurred, and still do occur at times, from the want of instruments to the unexpected approach of a train, or its undue delay on a particular part of the journey. Where there does not exist however an absolute necessity for such a system, its useless expense would be a powerful cause to adoption. In order therefore to meet the requirements of the railway in so economical a mode as possible, a modified system has been adopted. The same plan of divisions and of telegraphs, or rather telegraphy, which is adopted in the line, needles are dispensed with, and merely the ordinary telegraph retained at the subordinate stations. Usually the instrument possesses two needles and requiring two wires, is preferred for both the general and the sectional telegraph, as experience has shown that it is, taking all things into account, far superior to any other. The single-needle instrument, with one wire, is sometimes used for the small stations; but where the conditions are either of frequent occurrence or of considerable length, it has been found that it cannot be used with advantage, from the diminished rapidity of signalling, as compared with the double needle.

It is evident that in the system above described no subordinate station can communicate directly with another station beyond its own division. Intelligence therefore referring to a distinct portion of the line, would be sent in the first place to one or other of the terminal stations of the division, and from thence would be forwarded again as required.

In England, up to the present time, the electro-magnetic or mechanical telegraph (as it is called in contradistinction to the electric), was either of Professor Wheatstone's or Professor Cooke's invention; the former being adopted; the needle-instrument, from the great rapidity with which messages can be sent, and from other causes, having obtained the preference. It will however become very valuable, both as a means of working a permanent line, and also in some cases for the transmission of political or commercial intelligence, where secrecy is required. It is now in use in France, and has been entirely approved of. Within this last year or two a great and important improvement has been effected in the mechanical instrument, by the use of the electric current derived by induction from a permanent magnet, instead of the voltaic battery. This plan is not applied to the needle instrument, but is peculiarly so to the electro-magnetic telegraph; while at the same time a permanent and unalterable source of electric power is substituted for the galvanic battery. Although for telegraphic purposes these two instruments differ more than is generally supposed, their operations are singularly constant in their action, yet this is a most important advantage, owing as it does all necessity for change or renewal of the source of electric power.

This list does not include several lines on which the telegraph is yet only in partial operation or now being erected. Among such may be specified the Leeds and Bradford, Leeds and Manchester, Syston and Peterboro', Newcastle and Berwick, North British, Hull and Bradford, &c.

**TELEB-RISBUTH,** [TRELLAS] (P. C.)

**TEMPOPLEURUS.** Some fossil echinoids of the Suffolk crog are referred to this genus by Mr. S. V. Wood.

**TEMPERATURE OF THE SEA.** [SEA] (P. C.)

**TENT, MILITARY,** is a temporary dwelling-place made of canvas, which is supported by one pole, or more, and stretched by means of cords, which are made fast to pickets driven into the ground: tents are set up when an army is encamped in the field either for actual service or for the purpose of performing military exercises.

The tents of the private soldiers, whether infantry or cavalry, are of a conical form with circular bases, the supporting pole or standard of each being planted vertically in the ground, in the centre: the standard is 10 feet 8 inches long, and the whole diameter of the tent, between two opposite pickets, is 17 feet 3 inches; but from the lower extremity of the cone, about 2 feet from the ground, the canvas hangs down vertically and forms a cylindrical shell, therefore the diameter of the tent within the canvas is 13 feet 8 inches. Fifteen infantry, or twelve cavalry soldiers occupy such a tent. The round tent of an officer is 12 feet 6 inches in diameter within the walls. The marquees of officers, as well as the hospital and laboratory tents, are of oblong form on the plan, and in these, the canvas is supported by two standards, which are connected together at their tops by what is called a ridge pole 6 or 7 feet long. The length of an officer's marquee is 19 feet, and the breadth 18 feet, both dimensions being taken within the walls: tents of the two other kinds are still greater.

For the rules of modernod courier, or the dispositions of tents in an encampment, see Encampment, P. C.

**TENTACULITUS** is a beautifully formed group of small annulated pointed shells, fossil in the Silurian strata.

They have been recently referred by Mr. Salter to the Annona. (Reports of British Association for 1845.)

**TENTORII,** CRISTOFORO, born in 1745, in Spain, of a Venetian family, studied first in his native country, and afterwards removed to Venice, where he spent the greater part of his life. He is known chiefly for his historical works concerning Venice. He published, in 1765, his first work, 'Storia Civile e Politica della Repubblica di
VENETIA, con una Descrizione Corografica e Topografica de’ suoi Stati, Venice, 12 vols, 8vo. This was the first condemned history of Venice, being a kind of abridgment of the most usual histories of the republic, and especially of Sandi’s ‘Storia Civile e Politica,’ with the important addition of a topographical and statistical description of all the dominions of Venice. Tentori’s second work is a continuation of the first, being a full account of the destruction of the republic of Venice by the French in 1797: ‘Raccolta Cronologico-Ragionata di Documenti inediti che formano la Storia Diplomatica della Rivoluzione e Caduta di Venezia, di Adriano Cricchi, conservatori,’ 2 vols, 4to, 1799, published without the author’s name from prudential motives. Tentori consulted the secret state archives when they were first opened to the public after the fall of the old government, and there he found full evidence of the iniquitous arts by which the catastrophe had been effected. He gives the text of the documents in order of time, and accompanies them with a brief narrative of the events. The perusal of this work is absolutely necessary to form a correct idea of those transactions, and to counteract the erroneous impression produced by the garbled accounts published in France and in Italy; among the rest by an anonymous contemporary work entitled ‘Storia degli ultimi Ottocento anni della Repubblica,’ which was falsely attributed to Tentori himself. [VENICE, REPUBLIC OF, P. C.]

Tentori wrote about the same time an elaborate investigation of the history of the famous connection of Balmont Tlepo and the two Querni in 1809, which had been ignorantly asserted by the modern democrats of Venice to have been a movement in favor of popular liberty, whilst in reality it was the fruit of the tyranny of dispossessed patriots against their own order, and for the purpose of supplanting their personal enemy, the Doge Grazianos: ‘IL VERO CARATORE POLITICO DI BALSAMON TIPOLU, DIMOSTRATO DALLA VERSI COMPOSIZIONE DEGLI SAGGI VENETI ED ESTERI,’ Venice, 1789. The other works of Tentori are:—Della Legislazione Veneziana sulla Prescrizione delle Larghe, 8vo, Venice, 1792; ‘Dialogo sulla Regolazione del Fiume Brenta, con una Appendice di Riduzioni sopra il medesimo, corredata di una Carta Idrografica,’ Venice, 1790; ‘Errata-corrige sulle Memorie Venete del Gallicioli; ‘Osservazioni sulle Memorie eddette, Venice, 1797. Gallicioli was a contemporary compiler of Venetian history.

Tentori lived and died poor. He filled in the latter years of his life the office of preceptor in the patrician family of Tlepo at Venice. As a native of Spain he was required by Napoleon’s police in 1808 to swear fidelity to the intrusive king Joseph, which having refused to do, he was kept under arrest for a long time, and his papers were inspected by them at Bozen in 1810 at the country residence of the Tlepo family, at Carbonera.

(Tipaldi, Biografia degli Italiani Illustri; Moschini, Del Levante Veneziense.)

TERATOCRITHEUS, a fossil fish from Sheppoy. (König.)

TEREBELLARIA, a genus of fossil Milliporiae from the Bath oolite rocks. (Lamouroux.)

TEREBIA TYPHUS. This genus has been divided, according to the suggestion of Phillips (‘Paleozoic Fossil of Devon’), into Ephithria and Hypothyria. (Morris.)

TERENTIUS CLEMENS, a Roman jurist, whose period is uncertain, but he lived after Justinus, or was at least a contemporary, for he cites him. (Dig., 24, 6, 5, 8.) He wrote two books ‘Ad Legem Julianum et Papiam,’ from which there are some excerpts in the Digest. He is not cited by name in the Digest.

TERMS, ATTENDANT AND SATISFIED. As the assignment of satisfied terms on the purchase of property was frequently accompanied by great difficulty and expense, it was deemed advisable to remedy this increasing evil. In the 8 & 9 Vict. an act was passed intituled ‘An Act to render the assignment of Satisfied Terms unnecessary.’ It provided that every satisfied term on the 31st December, 1845, attendant upon the inheritance, should on that day cease, except that such term, although made to cease, should afford the same protection as if the same still subsisted, but had not been dealt with after the 31st December, 1845. And, by s. 2, that all subsequent terms, after created, and any not subsisting when the above was passed, should, on becoming satisfied after the day mentioned above, and which should after that day become attendant on the inheritance, should immediately on becoming so become attendant and determine.

The Bengal Presidency comprises the provinces of Bengal, Bahar, Benares, Allahabad, Oorans, Cuttack, Guundwa, the Ceded Districts on the Nerbudda, and the British territory east of the Ganges to the frontiers of Birma.

The Madras Presidency comprises the territory of the late Agra Presidency, which was established by an Act, 3 & 4 Wm. IV. c. 85 (August, 1833), but suspended by a subsequent Act, 5 & 6 Wm. IV. c. 92 (August, 1836), which empowered the Governor-General to appoint a lieutenant-governor of the North-West Provinces, and also from time to time to declare and limit the extent of the territory placed under him, and the extent of the authority to be exercised by him. The North-West Provinces extend east and north as to include the Delhi Doab, and the countries to the west and north of the Deli Doab; and probably include also the Jullundur Doab and hill-country connected with it, which is added to in our Table.

The Madras Presidency comprises the Northern Circars, the whole of the Carnatic, and extends westward across the peninsula so as to include all the British territory (Malabar, Canara, &c.) south and west of Myore.

The Bombay Presidency comprises all the British territory on the west side of Hindostan, from Canara northward, the Coopee, South Mahratta country, Deccan, Candelas, Surat, &c., and the islands of Hors and Quilon. The Bombay Presidency will probably be made to include Sinde, which was annexed to the British territory in March, 1845, and is yet (1846) under a separate governor.

The late conquests of the Lahore presidency on the east banks of the Ganges and Sutlege, and the Jullundur Doab, between the Beas and the Sutlege, with a considerable portion of hill-country which extends east-north-eastwards into the north of the Indus. By the treaty of peace with the Maharaja of Lahore, the British assume the control, in respect to tolls and ferries, of the Beas and Sutlege, the Ganges, and the Punjab to the confluence of the Indus and Ghulmutkaw, and the control of the Indus from Ghulmutkaw to the borders of Beluchistan.

The Madras Presidency is divided into Collectories for purposes of revenue and administration, but accounts are not published of the extent and revenues of the Collectories severally. A general statement of revenue is published for each Presidency. The last actual statement (not an estimate) is for the year 1843-4, as follows:—

The total amount of the public debts of the Presidencies, on the 30th of April, 1844, was £7,359,829, bearing annual interest amounting to £1,731,092.

British India, strictly speaking, comprises only the territory which is actually in the possession of the British government, but the whole of Hindostan, from the Indus to the frontiers of Birma, with the exception of Bengal and Oostindien, is under British suzerainty and control, and in fact forms one great political body, of which the British government is the head. Some of the Ootukudai, and other Collectories, are tributary, some are feudatory, and some are restricted, according to the circumstances and treaties under which they became dependent. The new Casmere state is feudatory. Ghohal Sing is to give to the British government annually 10,000, twan (a male and female), and three pairs of Cashmere shawls, as an acknowledgment of the supremacy of the British government. The government of Lahore is left independent, and the same annual tribute, limited by the new treaty to 25 battalions of infantry, consisting of 800 booyats each, and 15,000 cavalry. If a larger army should be necessary in any emergency, it may be increased by the British government; and the limits of the Lahore territory are not to be changed without a similar concurrence. All the dependent states are prohibited from making treaties of alliance with each other. The Portuguese still possess Goa, with a small territory around it, and the port of Damaun; the French, Pondicherry, Madav, and Carwali. Serampore and Tranquebar have been recently purchased by the British government from the Danes.

The circumstances which led to the annexation of Sind to the British territory are stated in the article S Kardash, P.C.S.C.

The late ruler of the Punjab, Ranjeet Sing, always remained on terms of amity with the British government in India, and had not only extended his territories, but also collected before the British government had been seriously seriously engaged in the Punjab. He was succeeded by his son, who having died, and the present Maharaja, Dhuleep Sing, who succeeded, being very young, his mother the Ranock was declared the successor of the latter, and became the head of the army, and in order to extricate themselves from the dangers to which they were constantly exposed from the violence of the soldiers, secretly gave its sanction to the leaders of the Sikh troops in making an attack on the British frontier. The Sikh army began to cross the Sutlege, Dec. 11, 1845, and, after investing Ferozepore on one side, took up an entrenched position at the village of Ferozepubah, about ten miles in advance of Ferozepore, and about the same distance from the village of Moodoke. In this camp the Sikhs had placed 105 pieces of cannon, and a force of upwards of 50,000 men, in order to intercept the British force which was advancing from Umbalick to the relief of Ferozepore, which had been attacked without provocation or declaration of hostilities. The British army, under Sir Hugh Gough, mounted on the 23rd December, in face of a rapid march of 150 miles, reached Moodkee, Dec. 18, and on the evening of the same day repulsed an attack of the Sikh army and captured 17 guns. On the following day the army was concentrated at Moodkee, and the Sikh army moved towards Ferozepore; and having on the march formed a junction with Major-General Sir John Littler, who had with him 5000 men and 21 guns, Sir Hugh Gough ordered the army in order of battle, and attacked the enemy's intrenchment of camp, and on the evening of Dec. 21 captured 74 pieces of cannon, took possession of the camp, with large quantities of ammunition and warlike stores, and compelled the Sikhs to retire to the Sutlege. The British force on this occasion consisted of 16,700 men, and 69 guns, chiefiy horse artillery. The Sikh forces were variously estimated at from 48,000 to 60,000 men, with 105 pieces of cannon of large calibres and fixed batteries. Sir Henry Dundie, governor-general of India, was engaged in this battle as second in command. The total killed of the British was 644, the total wounded 1721; in all 2415. The British took 21 pieces of cannon. The loss of the Sikhs must have been very large.

Major-General Sir Harry Smith having with much difficulty and loss of some baggage formed a junction with the troops at Loodiana, who were in a forbidding body of the enemy's troops, the Sikh army then retreated, and took up an intrenched position at Budawal, from which they were also compelled to retreat down the Sutlege, but having been reinforced by about 10,000 regular troops, taken up a strong position, and a large force of cavalry, from the right bank, the British advanced towards the British forces in order to intercept their communication with the main army, intimating themselves near the village of Alwai. The Sikh camp was carried by storm on the 25th of January, 1846, the whole of the enemy's cannon and munitions of war captured, and his army driven headlong across the Sutlege by a difficult ford. Fifty-six guns were taken by the British, and 11 others were sunk in the river. The total of British killed was 151, the total wounded 413, total missing 25; in all 589. The commander at the battle of Alwai was Sir William Willoughby, and the chief having on the same day been reinforced by Sir Harry Smith with the victorious army of Alwai, the attack on the Sikhs was made on the 10th of February. The enemy's camp, strongly intrenched, defended by 36,000 men, and 57
pieces of artillery of large calibre, with a considerable camp
and some artillery on the opposite bank of the river, was
stormed by the British army under Sir Hugh Gough, and
after two hours of desperate resistance on the part of the
Siaks, they were driven into and across the river with
immense loss, 67 guns having been captured by the British.
Sir Hugh Gough's success, however, suffered from the effects of
the fall, was also in this battle. The loss of the enemy is
supposed to have been from 8000 to 10,000 men. The loss of
the British was 320 killed, 2063 wounded; in all 2383.

The next day the British army retreated from the west
bank of the river, having been defeated in every action,
with the loss of a vast number of men and 220 pieces of
field artillery. The British army crossed the Sutlej, occupying
near the Maharaja Duleep Singh, his heirs and successors, on the other,
was concluded at Lahore, March 9, 1846. A similar
was concluded with the Maharaja Ghobal Singh at Umritsar,
or Umrit, March 16, 1846.

Sir Henry Hardinge has since been created Viscount
Hardinge, with an annuity of 3000l., and Sir Hugh Gough
has been created Lord Gough, with an annuity of 5000l.,
the annuity of 3000l. being paid to the next surviving
body of each of who may succeed to the respective titles; but
the Court of Directors of the East India Company having
granted to Sir Henry Hardinge an annuity for life of 5000l.,
paid by the East India Company, and the East India
Company, it was enacted that the government annuity of 3000l.
should not be paid to Viscount Hardinge till after the annuity
of 5000l. terminates; and an annuity for life of 2000l. having
been given to the Maharaja Duleep Singh on the 9th
of March 1846, the East India Company having paid
the Maharaja Duleep Singh, his heirs and successors,

TERTULLIANUS, Jurist. [Tertullianus, P. C.]

TERWESTEN, AUGUSTYN, was born at the Hague
in 1649. He became at about twenty years of age the pupil of
N. Wieling and W. Dousdus; before this time he had
maintained himself by working and chasing for goldsmiths
in 1673 he went to Italy, where he studied chiefly in Venice and
Rome, and visited France and England; and after an
absence of six years returned in 1678 to the Hague, where he
resided till his death, by his historical compositions, sacred and profane, but his favourite author
was Ovid. He restored the Academy of the Hague, which
did not come to a very inefficient state; and in 1690 he was
invited by the Elector of Brandenburg, afterwards King of
Prussia, to Berlin, and was appointed his court painter.
He contributed chiefly to the establishment of the Academy
of Berlin, of which he was made director. He died at Berlin
in 1711. He possessed with remarkable rapidity and freedom;
there are a few etchings by him.

TESBSED PAVEMENTS. [Tiles and Pavements, P. C.]

TEST ACT. [Boroughs, &c., P. C., p. 202.]

TESTE OF A WRIT. [Writt, P. C.]

TESTELIN or TETTELIN, LOUIS, was born at Paris
in 1646. He was the son of N. Wieling. He was elected
one of the original members of the French Academy, though
he was only thirty-three years of age at its establishment in
1646. His presentation picture was an historical portrait of
Louis XIV. He was appointed one of the professors of the
academy. Testelin's picture of the Resurrection of
Tabitha by St. Paul, painted in 1632, is considered one of the
master-pieces of the French school of painting, and is com-
pared with the celebrated picture by Rembrandt, the Burning of the Books at Ephesus; it is in the church
of Notre Dame; there is a print of it by Bosse and Picard to
Remain. There is also another celebrated picture by Testelin
in the church of Notre Dame deduced by the name of the
Sisters of St. Louis de la Charité, the same St. Louis who
was painted in 1656, the year of his death.

St. Louis attending a sick man, in the Hospital de la Charité,
is likewise a distinguished work by Testelin. As he died at
the age of 41, he was, in the east Indies, Sir Hugh Gough, and
Brun and Testelin were great friends. Testelin had great
theoretical knowledge, and he and Le Brun frequently con-
sidered on the principles of art. Testelin never was in Italy,
like Sir Hugh Gough, but he was a great admirer of comparative merit of the Roman and Venetian schools, taking
their abstract characterising as their subject, Roman design, and
Venetian colour and light and shade, Le Brun advo-
cating the grand style and French, added by a genius for
arguing the whole night through, Le Brun rose, saying, "My friend,
you have charmed me by your profound knowledge; the
victory is yours; certainly no man is better instructed in the
great masters than you are.

(D'Argenville, Abrége de la Vie des Peintres, &c.)

TETRAGONOLEPIS, a remarkable and numerous genus of
fossil gastropod fishes, chiefly from the lim strata of Dorset-
shire. [Agassiz.]

TETRANTHERA, a genus of plants belonging to the
natural order Lauraceae. The flowers are dioecious, some
hermaphrodite, involucrated. The calyx 6-parted, the seg-
ments nearly equal or wanting. The fertile stamens generally
about 9, in the petaloid flower from 12 to 21. The leaves
are variable, with pinnate veins.

T. ROZBYRUPHIS is a variable plant, a native of the mountains
of India and Ceylon. The leaves are elliptical, with the
base, smooth and shining above, more or less downy
beneath. The umbel rather compound and nearly white.
The fruit is globose, black, and about the size of a pea, yielding
a kind of fruiting powder 'the female part of the plant being
cut and dried. These seeds are a good quality candle, and which serves as a basis for
salves. This fixed oil is supposed to contain the principal
part of the fruit of Parcs gentianae, so much esteemed in the
East Indies under the name of A vondel Pea.

(Lindley, Vegetable Kingdom; Lindley, Flora Medica.)

TETRAODON. [Germkobutus, P. C. B.]

TETRAPRUS, a genus of fossil fishes from the Cre-
taceous and Tertiary strata. [Agassiz.]

TEXAS. This country lately formed a portion of the
territory of Mexico. The revolution through which it
became separated arose from the permission given to immi-
grants from the United States to receive grants of land. The
first permission of this kind was conceded to Moses Austin
in January, 1821, which on his death was extended to his son
Stephen Austin, and confirmed by the Mexican Cortes, April
14, 1823. These and other similar conceded were made on
condition of bringing into the country from 500 to 200 families
as the consideration of each grant of land.

Texas formed part of the State of Coahuila in the con-
federation of the Mexican States. It was established as a
state August 15, 1824, and the State Constitution was pro-
mulged in March, 1827.

In 1835 there was an open and undeclared war between the Mexican troops and the American settlers occurred. This was followed by various
conflicts; and at last the independence of the country was
proclaimed, when Stephen Austin advised that no limits of the territory must be marked, and that the field should be
left open to extend beyond the Rio Grande to Chihuahua
and New Mexico.

On the 2nd of March, 1836, a declaration of independence
was issued; and, on the 17th, a constitution was proclaimed, on
the model of those of the southern states of North
America. The law of slavery, which Mexico had abolished,
was re-instituted—the legislature was the power to enunci-
ate slaves—the presence in the country of free coloured
persons was interdicted, and the privileges of citizenship
were denied to all Africans, and the descendants of Africans and Indians.

On the 21st of April, 1836, the battle of San Jacinto was
fought between the Mexican and Texan forces, when the
president of Mexico, General Santa Anna, was taken
prisoner by General Houston. This event terminated all Mexican
authorities in Texas.

In 1837 the Committee of Foreign Affairs at Washington
reported to the House, that the independence of Texas ought
to be recognised. This recommendation was laid upon the
President of the Senate of Congress of the United States; and
the President of General Jackson, an amendment to the
General Appropriation Bill was carried, for the payment of
the outfit and salary of a diplomatic agent to Texas when
the President of the Senate of Congress of the United States
was a independent power. Immediately after this bill was

exposed to the sun, that these are often cooled below the temperature of freezing water; and while in this state, if a current of warm air pass over their surfaces, the water which the air holds in solution deposits itself on the walls, where it is converted into ice or snow; it remains thus frozen for a time after a thaw has commenced, but at length, the temperature increasing, the ice is melted and the walls are then covered with moisture.

It is often remarked that at the time of a thaw taking place there is felt a degree of coldness greater than that which is experienced during the continuance of the frost; this is apparently caused merely by the evaporation of the moisture which is then on the skin, for the thermometer at the same time indicates an elevation of temperature in the atmosphere.

The overflowing of rivers by the dissolution of the snow and ice on the mountains about their sources is well known, and to the liquification of the ice formed by the previous congelation of water which has introduced itself in the fissures of rocks is to be ascribed the occasional occurrence of large masses from the sides of mountains; the expansion of the water in freezing having destroyed the cohesion, so that the parts are only held together by the ice, and on the liquification of this the disunion is complete.

THESES. The writer of the article Thebes, P. C., has, owing to a misapprehension, given references to Carnac and Luxor, instead of describing them under the article Thesee. We now supply the omission.

On the site and amongst the ruins of the ancient city of Thebes stand four principal villages, Carna or Luxor on the eastern bank of the Nile, Geurnon and Medinet-Ahun on the western bank. At Luxor, near the river, are the remains of a temple, the entrance to which is through a magnificent propylon, or gateway, consisting of two pyramidal masse, the

A severe and long-continued frost abstracts so much caloric from terrestrial bodies, as the walls of buildings which are not

signed by the President, the nomination of a Chargé d'Affaires of Texas was sent by him to the Senate and consented to by it—and thus it was, that the Republic of Texas was recognized by the United States. To have effected this recognition by treaty, a majority of two-thirds of the Senate would have been required, but a majority could not then have been obtained. A mere majority was sufficient to confirm the nomination of a chargé d'affaires.

On September 25, 1839, a treaty was signed between France and Texas, and was ratified at Austin, Jan. 18, 1840. This was the first recognition of the independence of Texas by a European power. On Nov. 16, 1840, a treaty between Great Britain and Texas was signed, which was ratified at Austin in Feb., 1841. This treaty was made with the governments of the United States and Texas; and in consequence of no such treaty being required as a condition precedent to the recognition of Texas independence by this country, the nomination of Texas in the United States was greatly facilitated.

The government of Mexico persisting in its refusal to acknowledge the independence of the country, proposals were made to annex the republic to the United States. The trade and security of the people settled in the western district were constantly disturbed—narrating incursions were common, and the government had not necessary resources sufficient to enable it effectively to carry on a war. It had been hoped that the influence of France or of Great Britain would have checked the evils arising from the obstinacy and weakness of the Mexican authorities. Seeing that this did not happen, public opinion began to favor intervention by the United States, and this feeling was further stimulated by the efforts of Presidents Tyler and Polk, both of whom strongly urged upon the Congress of the United States the policy of taking advantage of the opportunities afforded by the political condition of Texas. On the passing of an Act by the Texas Congress to surrender its independence, in December, 1845, an Act of Congress of the United States declared Texas to be one of the States of the North American Union. The boundary between Texas and the United States was fixed by the Florida Treaty of 1819. The Congress of Texas declared the western limits of Texas to extend to the Rio Grande, including the department of New Mexico, which had never formed part of the State of Texas or Coahuila, and was settled by the Spaniards as early as 1605. The government of the United States, since the annexation of Texas, appears to make a claim to the same extent of territory, and there is also every probability that one of the results of the pending war with Mexico will be to extend the authority of the United States over the entire province of California.

(Address of J. Q. Adams to the Electors of Massachusetts, September 12, 1842; Kennedy's Texas; Congressional Documents of the Senate of the United States, 1846; Falconer On the Discovery of the Mississippi, 1844.)

THaw is the reduction of ice or snow to a liquid state in consequence of an increase of temperature. This effect is produced on the surface of the earth or in the atmosphere during the spring season by the return of the sun to the hemisphere of the observer, the solar rays then falling in greater abundance than before on a given extent of ground; or it is produced by accidental currents of warm air which pass over a frozen mass. The dissolution of the particles of ice in the atmosphere is the cause of the humidity which accompanies a thaw.

As the conversion of a liquid into ice always commences at the surface of the former, and about the sides of the vessel containing it, or about those of a solid body immersed in it, so in ice surrounded by air which has acquired a higher temperature than the ice has, the process of liquation commences at the sides and extends gradually from thence inwards; ice being a bad conductor of heat, the central parts of it are the last which are dissolved. It is observed that when solid bodies, whose temperatures are equal to one another and higher than that of ice, are applied to the latter, the ice is dissolved more rapidly by those which have the greatest power of conducting caloric; thus a piece of ice being laid on a plate of polished metal, and a piece of equal magnitude on wood, the ice on the metal will be dissolved before that which is laid on the wood, not only when the temperature of the metal and wood are equal, but even when the temperature of the wood considerably exceeds that of the metal, the latter conveying more abundantly to the ice the caloric which it is continually removed from it and conveyed with elaborate sculptures, stood two of the most perfect obelisks known to exist, one about 82 feet high, the other 76, and from eight to ten feet wide at the base. The

Vol. II.—4 L

Digitized by Google
smaller obelisk has been removed by the French, and now stands in the Place de la Concorde at Paris. A ship constructed expressly for the purpose of transporting the obelisk sailed from Alexandria on March 25, 1833. The smaller obelisk was selected as not only lighter, but in a better state of preservation than the larger. This obelisk was found to have been placed on a higher pedestal than the other, and somewhat more forward, so as to make the difference of size less observable to the spectator. The obelisk was lowered, conveyed to Paris, and erected Oct. 25, 1836. The cut on the preceding page presents a view of the two obelisks with the pedestal behind them, and a portion of the ruins of the interior of the temple.

But the remains of Carnac, about a mile and a quarter lower down the river, are still more wonderful than those of Luxor. An irregular avenue of sphinxes, 3180 yards in length, connects the southern entrance of Carnac with the northern entrance of the temple of Luxor. Carnac is about 830 yards from the east bank of the Nile, and is surrounded by a wall of unburnt bricks about 8500 yards in circuit, or more than three miles. An adequate idea of the extent of the remains in this inclosure could only be given by a plan on a large scale. The largest of them, which some have thought to be a temple and some a palace (it may have been both) is 1856 feet in length, 360 feet in its greatest width, and 321 feet in its least width. The entrance to it (the western entrance) fronts the Nile, with which it is connected by an alley of columns, the tops of which are formed of a lion and a human head (a ram). This alley conducts to a propylon, without sculpture, 360 feet long and 145 feet high, with a great doorway in the centre 64 feet high; passing through which a large colonnade forms a range of pillars on the sides, and a double row of slabs on pillars down the middle, which terminate opposite two colossal statues in front of a second propylon. A flight of twenty-seven steps then leads to the entrance hall, which has been called the Great Portico of the House of Carnac. It is 338 feet by 1704 feet, and comprises an area of 37,629 square feet. The roof, which is flat, and when perfect was formed of very large slabs of stone, is supported on the columns of the arcade, which are about eleven feet in diameter and the smallest nearly nine feet. Four churches of the size of that of St. Martin’s in the Fields, London, might stand side by side in this vast hall without occupying the whole space. The interior propylon, pillars, and walls are covered with sculptures. Four beautiful obelisks form the entrance from the hall to the adyta, or sacred place, which consists of three apartments, all of granite, and the sacred room, or sanctuary, is adorned with rich sculptures, and paintings and gilding. Beyond the adytum are porticoes and galleries, which were probably continued to another propylon at the eastern end.

The adytum consists in front of them, form the entrance on the south side, at the end of the long avenue of sphinxes leading from Luxor; and there was probably a similar entrance on the north side.

Painting Knowledge,' 'Egyptian Antiquities,' vol. i., 'Penny Magazine,' 1837.

THEOTOCPFALI, DOMINICO, called El Greco, was painter, sculptor, and architect. He is said to have been the scholar of Titian. In 1577 he was residing in Toledo, where he appears to have settled, from his name and his surname of El Greco, the Greek, he was doubtless a native of Greece. He painted many pictures in Toledo, and acquired a great reputation in Spain. El Greco made the marble decorations of the altar (retablo), and the altarpiece of the Parting of Christ’s Raiment before the Crucifixion, for the old sacristy of the cathedral of Toledo, which was occupied from 1577 until 1687, when he was paid for the whole work 319,600 maravedis, of which 119,000 were for the picture; about 100,000, altogether, but owing to the change in the value of Spanish money it is perhaps impossible to calculate the sum accurately. He was however not engaged exclusively on this work all this time; he painted other works in the meanwhile, and for Philip II. an altarpiece of the Martyrdom of St. Maurice for the cathedral, which he never had the opportunity of completing. It is now in the chapel of the college; a picture by Romulo Casarrubios was substituted for it over the altar of the chapel of St. Maurice’s in the Escorial. The study of these pictures was the main hardness of colour and extravagance of design which El Greco is said to have introduced to prevent the picture being mistaken for a work of Titian, which it seems had been the fate of some of his best paintings.

As an architect he designed the Cua del Ayuntamiento or mansion-house, of Toledo, and the churches of La Caridad and of the convent of the bare-footed Franciscans at Illlescas; and he designed also the whole of the paintings and sculptures of these churches. In 1590 he designed the church of the Augustines at Madrid, called de Donna Maria de Aragon, and painted the principal altarpiece of their college. He designed also several monuments, which are among his best works. He died at Toledo in 1652, according to Palomino, seventy-seven years of age; and was buried with great pomp in the church of St. Bartholomew.

El Greco’s pictures were still more numerous at the end of the last century; Cean Bermudez enumerates a great many in Toledo, Illlescas, Escalona, Bayona, in Segovia, La Guardia, Mostoles, Casarrubios, Siguenza, Medina Celis, Valencia, Leon, at the Royal Palace in Madrid, and in many other places. Many have been removed. Mr. Ford, in his 'Handbook of Spain,’ notices only three pictures by this painter—Christ bearing his Cross, and a Nativity, and an Adoration, in the Salón de la Sacrificia at Toledo.

Richard Cumberland speaks in high terms of the pictures of El Greco, especially the Preparation for the Crucifixion and the Parting of Christ’s Raiment in the cathedral of Toledo, already mentioned, and the entombment of Don Gonzalo Ruiz, Count Orgaz, in the church of Santo Tomé at Toledo, which he considers his masterpieces. The first he terms a grand composition, so entirely in the style and manner of Titian, that it is the true spirit of the Spanish school, and of its adoption. The burial of the Conde de Orgaz was painted in 1584 for the archbishop of Toledo, Cardinal Don Gaspar de Quiroga, for the great sum of 2000 ducats according to Cumberland. In the churches of St. Maria la Real and St. Augustine convent of San Estevan at Toledo, and this picture was painted in honour of the foundation—the saints Augustine and Stephen are represented deposing the crown in his hand, and the picture contains the portraits of many distinguished persons of the time.

His son, George Manuel Thotococufali, was also a sculptor and architect of eminence. He was appointed painter and architect to the King of Spain, and died in Madrid while he was on a journey to Paris, and he died at Toledo in 1631. He was the architect of the ceanav of the church of the cathedral: it is an octagon decorated with precious marbles and a painted dome, and is used as the treasury-house of the Virgin, where her splendid dresses are kept, as well as many precious relics.

(Cean Bermudez, 'Diccionario Historico,' &c.; Cumberland, 'Anecdotes of Eminent Painters in Spain.'

THILOBUS, a fossil fish from the upper Siurian strata of Lodlow. (Murchison.)

THEONOA, a genus of fossil Zeolitha from the secondary and tertiary strata. (Lamouroux.)

THIBAULTIUS JUSTUS BRIEDEKIND, a celebrated German jurist, was born on the 4th of January, 1772, at Hameln in Hanover. In 1792 he went to Göttingen to study the law; he continued his studies at Königsberg; and he finally settled at Kiel, where he was also acquainted with Niebuhr. In this university he took the degree of D.C.L., and in 1796 was admitted as a junior teacher of the law. He soon rose to eminence, and at the age of twenty-seven was appointed ordinary professor of civil law. In 1802 he went to the same capacity to Jena, where he published his 'System des Pandekten-Rechts,' the first systematical attempt of the kind that was written in the German language, the former works on that subject having been written in Latin. The merits of this excellent work were generally acknowledged, and Thibaut was chosen by the Emperor Alexander one of the foreign members of the commission of legislation for Russia, in 1812. In 1823 he was made professor of the university of Heidelberg, where he remained till his death. Though scarcely passed thirty, he was considered to be the first civilist in Germany after Hugo, Savigny having not yet attained his great reputation. Twice Thibaut was the principal, or professor of the university of Heidelberg, and nine times he filled the office of dean of the faculty. He was also chosen deputy of the university in the first chamber of the States of Baden, but as he now resided in Poznan, he resigned the office. In 1826 he was made a privy councillor. His fame and his popularity among the students led to his receiving invitations from other universities, as for instance from Leipzig, where the then professor of philosophy informed him with a very large income, besides a prebend in the chapter of Merseburg; but nothing could induce him to leave Heidelberg. In 1830 he was knighted by the Grand-Duke of Baden.
his former pupil, who in 1834 appointed him judge for the grand-duchy, in the newly established tribunal of arbiters for the dominion of Baden. In 1818 he was chosen Meister corresponding à l'Académie des Sciences, Moralphilosophie, et Politiques, for the section of legislation and jurisprudence. Thibaut died on the 28th of March, 1840, with the well-deserved reputation of being equal to Savigny as a civilian, and superior to him as a teacher and practical jurist. The great object of Thibaut was to distinguish clearly between the obsolete portions of the Roman law, and those which were of real practical use. In his private life Thibaut was most amiable: to many a poor scholar he proved a kind father; to many who had talent, a wise friend. His house was open to all his pupils, whether introduced to him by others or by themselves; but he showed particular attention to those who, beyond the ordinary means of knowledge, had the means of which he was a profound judge. His little work on Purity of Music quoted below is a specimen of his refined taste in this respect.

The principal work of Thibaut is his 'System des Pandekten-Rechts,' mentioned above, of which the eighth edition was published at Heidelberg in 1834, 2 vols. 8vo., and a ninth edition since the author's death, by Professor Buchholz, Jena, 1846. This work is in the hands of nine out of the ten lawyers in Germany, but though of the highest value, it is rather a difficult book to beginners. The following are the other works of Thibaut according to the date of their publications: 1. 'De principiis jure divisio Pretio,' 1768, 8vo., a dissertation inaugural which brought the young honours of being attacked by Hugo. 2. 'Jurisprudentia exequipolitica et methodoligica,' 2 vols., 1789, 8vo., the 'Einzelne Theile der Theorie des Rechts.' ('Essays on several Branches of the Theory of the Law'), Jena, 1788-1802, 2 vols. 2nd edit., 1817, translated into French by De San dit et De Chassaing, Paris, 1811. 4. 'Rechts Besitz und Verjüngung' (On Possession and Prescription), Jena, 1802, 8vo., a work which caused a great sensation, but was afterwards thrown into the shade by Savigny's work on Possession. 5. 'Besitz und Verjüngung,' 3 vols., 1814, 4th edit., 1822. 6. 'Ueber Reinheit der Tonks.' (On Purity of Music), Heidelberg, 1825, 8vo.; 2nd edit., 1826. 7. 'Ueber die Nothwendigkeit und Nützlichkeit des Gesetzes,' 2 vols., 1814, 8vo. ('On the Necessity of a Common Code of Laws for Germany'). This work placed its author at the head of a great legislative movement, and a short explanation is necessary in order that the reader may understand it. Almost German laws and a large portion of the Roman law exist there together, the former referring principally to landed property, entails estates and others called 'noble estates,' the latter to the public law of the Empire, and the personal law, in the succession to such estates, the legal consequences of marriage inasmuch as it effects complete commutation of property, personal and real, between husband and wife, furlough, marriage and testamentary custom. Among its contracts, the common succession to personal property and to land, except entails estates either noble or villain, testaments (in a great measure) and many other things are regulated by the Roman law. In some parts of Germany the German and Roman elements of the law are knitted together by modern legislation into a regular code, civil and criminal, as the Austrian code; the Prussian, which is in force in the greater portion of the kingdom of Prussia; the Bavarian criminal code, the work of Feuerbach, in Bavaria and Oldenburg. But the civil law in the latter two countries and nearly the whole of Germany, except Austria and Prussia, is that compound of Roman and German elements which has been mentioned above. Besides the 'Common Law,' by which is meant the Roman-German compound aforesaid, there is a variety of provincial and local laws, among which the laws of the cities of Magdeburg, Hamburgh, and Lübeck deserve a particular attention, especially the law of Lübeck. The Roman-German code is not only presented in the form of a code, but is the common law of nearly all the towns of North-Eastern Germany as well as those in the adjacent provinces of Eastern Prussia and the so-called German provinces of Russia. In the twenty years of the time of the 'Rhineinlandstatistik' in 1796, the French code became the common law in the Rhineland provinces and in the grand-duchy of Baden.

This sketch, however imperfect, may be sufficient to show that the government of Austria, though but little, is not in the least interferent; and that the difficulties increase in proportion to the extent of the jurisdiction of the different courts; and hence the strange, yet under such circumstances necessary fact, that the faculties of law in the various universities were, and partly still are, so many courts of justice before which cases need to be brought, that no one could expect more regular or more practical instruction, especially in historical learning, than is generally possessed by the members of the common courts of justice. Thibaut's proposal was to fashion this legal chaos into a general code, as was done in France; and although he admitted that the task would be very difficult, he maintained that what had been done in France would diminish the difficulty. His plan became soon popular, but he also met with decided adversaries, among whom Savigny took the lead, who contended that Germany was not yet ripe for 'a common legislation; that the idea itself was good, but that there were so many scientific (rather theoretical) differences among the jurists concerning the most important points, that every attempt would prove abortive till matters had previously been settled scientifically.' Savigny also could refer to an example, the Prussian code ('Landrecht'), which, though only an experiment upon a portion of Germany, is yet considered to be a failure: he avoided speaking of the Austrian code. At present the opinion of Thibaut has more adherents than that of Savigny; and since the latter's views depend merely upon an eventually which cannot but take place, however soon it may be, it is to be presumed that the period when Germany will enjoy a common code is not so very distant. Thibaut has entered into many details concerning that important question in several of his numerous essays, dissertations, and books. He was the founder of the 'Civilistisches Archiv' and the 'Heidelberger Jahrbücher.'

(Den Gadeus's Dictionary; Babington, Manual of British Botany.)

THORVALESEN, BERTEL (Albert), was born November 19, 1770, at Copenhagen. He was the son of Gottschalk Thorvaldsen, a carver in wood, and his wife Karen Grønfeldt, the daughter of a priest of Jutland. Gottschalk was a native of Iceland, and was in very poor circumstances when his son Bertel was born. Bertel and his father in his work at a very early age, and when only eleven years old he attended the free school of the Academy of Arts at Copenhagen, and made such progress in two years that he was enabled to acquire a considerable knowledge of his art, and to undertake to execute the head-pieces of ships. At the age of seventeen he obtained the silver medal of the academy, for a law-relief of Cupid reposing; and in 1791, when he was only twenty years of age, he presented a sketch of Helliodorus driven from the temple. Two years later he obtained the principal gold medal of the academy, and with it the privilege of studying for three years abroad at the public expense under his father's direction. He devoted a year or two to preliminary general study, for scholarship was not one of his acquirements, and he had much
to read and much to learn. On the 20th of May, 1796, he set out for Italy in the Danish frigate Theis, and he arrived at Naples in the end of January of the following year, in the packet-boat from Palermo. The Theis cruised in the North Sea until September; but the Danish government then allowed a period of quarantine at Malta, made a voyage to Tripoli to protect Danish commerce, and performed quarantine a second time at Malta, when Thorwaldsen left it in a small sailing boat for Palermo, where he took the packet-boat to Naples.

At Naples, wholly unaccustomed to the Italian language, and for the first time entirely separated from his own countrymen, 28-year-old Thorwaldsen's heart failed him, and he longed to return to Denmark, which according to his own account he would have done if he had found a Danish vessel about to leave the port at the time. However, in a little time he found courage to engage a place in the crew of a vetturino for Rome, where he arrived March 8, 1797.

Thorwaldsen brought letters of introduction to his distinguished countryman Zoega, who however did not give the young sculptor much encouragement, nor did he estimate his ability very high. When Zoega was once asked what he thought of him, three years after his arrival, he answered with a shake of the head, 'There is much to find fault with, little to approve with, and he will never succeed in his industry.' Alas! during this time Zoega was right, except in the last particular. Thorwaldsen was industrious, but faddish, and often destroyed what he had cost him much labour. This was the fate of a deeply-reflecting mind which he had to modelled to take back with him to Copenhagen at the expiration of his term of three years allowed by the Academy. He however made a second attempt at the same figure, and this statue was not the least difficult Zoega, with whom Thorwaldsen was about to return to Denmark; and Canova exclaimed, 'This work of the young Dane is in a new and a grand style.'

By the assistance of a Danish lady, Frederica Brun, who gave him the necessary funds, which he did not, and that the statue in song, it was cast in plaster, and Thorwaldsen prepared for his return home: but when on the point of starting and about to step into the carriage of the vetturino, one of his commissions, the Danish sculptor Hanges, found that his passport was not in order, and he was obliged to put off his journey until the next day. Thorwaldsen determined to wait with him, the vetturino started without them, this delay was followed by another, and it eventually happened that Thorwaldsen did not return to his native country until 1819, after an absence of twenty-three years. The liberality of Thomas Hope was the immediate cause of Thorwaldsen's finally settling in Rome. The works of Owans upon the statues of Jason, of Copenhagen were repeated in the artistic circles of Rome, and echoed by the professional dilettanti of the place. One of these dilettanti took Mr. Hope in the year 1803 to the studio of Thorwaldsen, to see the statue with which he had praised. The English connoisseur stood long before the plaster figure, then inquired what Thorwaldsen required for a marble copy of it: ' 600 ducats,' was the answer; 'You shall have it,' said the sculptor, without waiting his reply of assent.

From this time the star of Thorwaldsen was in the ascendant; the statue was however not finished until many years afterwards, but many celebrated works were done in the meanwhile; as the bas-reliefs of Summer and Autumn, and the dance of the Muses on Helicon; Cupid and Psyche; and Venus with the apple. His fame spread far and wide, and Christian, the present king (then crown-prince) of Denmark, wrote him a pressng invitation to return to Copenhagen, communicating at the same time the discovery of a white marble quarry in Norway. Thorwaldsen was eager to return, but commission upon commission rendered it impossible; he could not leave the capital city.

During this busy time Thorwaldsen recreated himself in the summer seasons at Leghorn, in the beautiful villa of Baron Schubart, the Danish minister at Florence: he executed also some of his works here.

In 1812, when arrangements were being made for Napoleon's visit to Rome, the architect Stern, who superintended the preparations, happened to sit next to Thorwaldsen at one of the tables in the Catholic church of St. Luko, and asked him if he could get ready a plaster fresco for one of the large apartments of the Quirinal Palace, in three months. Thorwaldsen undertook the commission, and in three months the plaster sketch, a celebrated bas-relief of the Triumph of Alexander was completed. The immediate subject was Alexander's triumphal entry into Babylon: the frieze is 160 Roman palms, its height five palms: it has been twice executed in marble, with slight variations, and is engraved in a series of plates by S. Amsler, of Munich, after drawings by Overbeck and others.

In 1813, Thorwaldsen and his friend the artist at Algiers, took a voyage to the islands of Cythera and the Paphos, and in a single day, two of his most popular works, the bas-reliefs of Night and Day; but he had done nothing whatever for weeks and months before. In July, 1819, he started in the company of two friends on his first visit to his native land, and he arrived at Copenhagen on the 3rd of October of the same year: his parents had died some years before. His fame was now so well established, that even through Italy and Germany his journey was a splendid triumph and his termination of term was lodged in the palace of Charlottenburg and entertained with public feasts. In about a year he left Copenhagen and returned to Rome through Berlin, Dresden, and Warsaw, where he received several commissions, and made a bust of the Emperor Alexander.

He executed his principal works after his return to Rome, as Christ and the Twelve Apostles; the group of St. John in the Wilderness; and the monuments to Copeninors, Pins VII, Maximilian of Bavaria, the Pontiatiok monument, and others. In 1823 he had a narrow escape of his life: a boy, the son of his landlord, contrived to get hold of one of Thorwaldsen's pistols, which was discharged in his hand, but with a good heart, and afterwards he continued his art with the same success. In 1825 he was appointed to the post of Frigate Capt. of the frigate Rota to carry them and their sculptor to Copenhagen. Thorwaldsen was received with enthusiasm by his countrymen; and he remained among them on this occasion about three years, and finally left them to engage his services in the service of the Baron Stampil, where a studio was built for him; and he finished here some of his last works—the frieze of the Process to Gogolofa, for the cathedral; the entrance into Jerusalem, for Copenhagen; and the busts of the poet Oehlenschlager and Holberg.

In 1841, finding the climate disagreeable with him, he felt compelled to return to Italy, and he executed at this time his group of the Graces for the King of Wurtemberg. He returned however to Denmark and Nyso in the following year, and executed two other works, bas-reliefs, which are among his last productions—Christ's Joy in Heaven; and the Genius of Poetry, which he presented to his friend Oehlenschlager. He intended to return to Rome in the summer of 1844, but he died suddenly in the theatre of Copenhagen, on March 24th, in that year, aged seventy-three: he was buried in the Church of Christianshavn, and the Danish government sent the frieze Rota to carry them and their sculptor to Copenhagen. Thorwaldsen's will bears much resemblance to Sir F. Chantrey's will: he left 60,000 dollars to the Danish National Museum, including casts of his own works, to the city of Copenhagen, to form a district museum, which was to bear his name, on the condition that the city furnished an appropriate building for their reception. This building was nearly completed before the death of Thorwaldsen; 60,000 Danish dollars were subscribed already in 1842, and the museum fast approaches its completion. Beside casts of the numerous works of Thorwaldsen, which would alone constitute an imposing collection of its class, it contains many works of ancient and modern sculpture, numerous paintings by old and recent masters, casts, vases, engraved gems, cameos, terracottas, bronzes, medals, cameos, engravings, prints of all descriptions, books on the fine arts, and drawings. With the exception of 12,000 dollars to each of his grandchildren, and the life-interest of 40,000 dollars to their mother Madame Poulsen, his natural daughter, to descend to her children, the whole remainder of his estate is to be converted into capital, and to be added to the 25,000 dollars already presented for the purpose by Thorwaldsen, to form a museum perpetual fund, for the preservation of the French National Art, for the encouragement of Danish art, and to add to the collections of the museum. His daughter, now a widow, resides in Rome, where she was born. Thorwaldsen's will is to be completed by Professor Bissen, of the Academy of Copenhagen, and he is superintendent or keeper of the Thorwaldsen Museum; the
THO

629

THY
government is with five trustees, two are always to be pro-
fessors of the Academy, one a magistrate of Copenhagen, and
one a sculptor, and one a lawyer. Thorwaldson, himself a
trustee, and all questions are to be decided by a majority of
voices. The trustees themselves will supply all vacancies as
they occur. There are at present six, but the perpetual num-
ber is ten.

Thorwaldson is considered by his admirers the greatest of
modern sculptors, and many have not hesitated to place him
far above Canova, and to compare him with the antique. This
is however hardly the rank he will hold with posterity; his
style is uniform to monotonity, though many individual
figures are bold, solid, and of beautiful proportions. His
 beau-ideal appears to have been something between the An-
cient Greek and the Christian type. Degasmet called him a
Grecian; but as his subjects are seldom heroic, he seldom
required more than a moderate expression of heroic vigour or
robust strength and activity: in this respect, and in execution
generally, he was much surpassed by Canova; but still more
so in the grace of the female form, in which Thorwaldson cer-
tainly did not excel. His females are much too square in the
frame, the head and shoulders being generally heavy; and in
no instance do we find in his female figures, in full relief,
that beautiful undulation of line and development of form charac-
teristic of the female, which is displayed in the antique, in
the works of Canova, and in those of some other modern sculptors,
as well as of the master of Grecian sculpture. Bagophanes
customarily was a favourite style with Thorwaldson, and a
great proportion of his works are executed in this style. Of
this class some of his minor works are the most expressive; but
the whole of this group is somewhat cold-blooded. The
Church of the Bois de Boulogne was an occasion to Golgotha,
which is the frieze of the cathedral church of Copenhagen,
immediately below the numerous group of John preaching in the Wilderness,
in full relief, in the red marble; in the same building, the four great Prophets;
Christ and the Twelve Apostles are above and around the
altar. The Triumph of Alexander, of which there is a copy in
marble in the palace of Christianstadb (the first marble copy
was executed by Canova, and is now in the Villa Farnese in
the Lake of Ceno), is a long triumphal procession in two
divisions, one meeting the other. In the centre, Alexander,
in the chariot of Victory, and followed by his army, is met by the goddess
of Peace, followed by Mazzocchi and Bagophanes with presents
for the conqueror. The subject is taken from the work of
Quintus Curtius. Much of the frieze is symbolical; per-
spective is nowhere introduced. The whole arrangement is
beautiful, especially that portion which comes from Babylon,
comprising the General Mazzocchi with his family; female
figures strewing flowers; Bagophanes placing silver altars
with burning incense, musicians, and attendants leading horses,
archers and military, and other various figures; but the
next to these are symbolic representations of the river
Euphrates, and the peacefull occupations of the Babylonians. The
human figures of this work are admirable, as is also the
marble which has been selected. The general mediocrity both in design and modelling, especially that of Alexander himself, Bucephalus, which is led following
the chariot of Alexander; it is a complete distortion. None
of the horses of Thorwaldson are successful. The colossal
animal of the Poniatowski monument at Warsaw, and that
of (smaller proportions) of the monument to Maximilian of Bavaria
at Munich, are heavy and graceless, and wanting in the finer
characteristics of form which belong to the horse. The works
of Thorwaldson do not display extraordinary power or fertility
of invention - Flaxman's distinguishing faculty. Flaxman's
outlines belong not less to the province of sculpture from the
circumstances of their not having been executed in marble;
most of them are designed and well adapted for basso-
relievo.

Many years ago some admirers of Lord Byron raised a sub-
scription for a monument to the poet, to be placed in West-
minster Abbey. Christmas was requested to execute it, but
on account of the smallness of the sum subscribed, he declined,
and Thorwaldson was then applied to, and cheerfully under-
took the execution. In 1845, Thorwaldson was commissioned
to execute a monument at the custom-house in London, but, to the astonishment of the
subscribers, the Dean of Westminster, Dr. Ireland, declined
to give permission to have it set up in the Abbey, and owing
to this difficulty, which has proved insurmountable, for the
present decree that it shall not be executed. Since his decease,
it has remained for upwards of ten years in the custom-house,
and has recently (1854) been removed to the library of
Trinity College, Cambridge: it was previously taken to the
studio of Sir Richard Westmacott. The poet is represented
of the size of life, seated on a ruin, with his left foot resting
on the fragment of a column and his right hand holding a
style up to his mouth; in his left is a book, inscribed 'Childe
Harold,' he is dressed in a frock-coat and cloak. Beside
him on the left is a skull, above which is the Athenian owl.
The execution is not of the highest order; both figure and
bas-relief are arcquately modelled; thus fineness of expression is
precluded through want of elaboration. The likeness is of
course posthumous.

(II. C. Anderson, Bertel Thorwaldsen, eine biographische
Skizze. Aus dem Dönhnischen übertragen von Julius Reucher,
Kunsthblatt, 1844; Art-Union Journal, 1845.)

THRCINCIA, a genus of plants belonging to the natural
order Composita. The leaves are pointed, figure-shaped;
are sacculated; thus fineness of expression is pre-
cluded through want of elaboration. The likeness is of
course posthumous.

(THUNBERG's Hist. of Plants.)

THUYDIES, a genus of fowl coniferous plants from the
colloque of Stonesfield, Collyweston, Gristhorpe, and Solen-
hofen. (Bronnlaert.)

THYMUS, the subdivision of the genus SCOMBER
(Mackerel) to which the fish called the Tunny belongs.
The Tunnies differ from the Mackerels in the position of their
first dorsal fins, which, instead of being separated from the second
by a wide interval, are prolonged close to the head. In the
thorax they have a corset of larger scales, a character which
is wanting in the subgenus Scopem. The Tunny and Bonito
are the best known examples. The former fish has nine
broad, continuous fins above and below; the latter has eight above and
seven below.

The general form of the tunny resembles that of the
mackerel, but it is thicker in proportion to its length. The
face is black with a white border below; the head is white;
the belly is grey, with silver spots; the fins variously coloured;
the first dorsals, pectorals, and
ventrals are dusky; the tail is rather paler; the second
dorsal and anal more or less flesh-coloured, and the spiny
fins sulphur-yellow, edged with black. The tunny grows
to more than seven feet in length, and when of those
dimensions weighs more than four hundred and sixty pounds.

The following interesting account of the modes of fishing
the tunny in the Mediterranean is given by Mr. Yarrell in his
'History of British Fishes':—

"In the months of May and June, when seeking a proper
situation near the shore upon which to deploy their spawn,
the adult fish rove along the coast in large schools and are
known to be extremely timid, easily induced to take a new
and apparently open course to avoid any suspected danger.
Advantage has been taken of these peculiarities to carry on
most extensive fishery against them at various places, which is
as valuable as it is destructive. Cutler and M. Valenciennes
have described the two most common modes of effecting their
capture. When the fish are provided with a long line
stretched a few yards in front of the boat, or held in a circle,
and joining their nets form an inclosure which alarms the fish,
while the fishermen drawing closer and closer, and adding
fresh nets, still continue driving the tunnies towards the
shore. When they have reached the shallow water, a large
net is used, having a cone-shaped tunnel to receive the fish, which is drawn towards the shore, bringing with it all the short boats. The carters carry the fish in great bunches, and small tans
in their arms; the larger are first killed with poles. This fishery, practised on the coast of Languedoc, sometimes yields many hundredweight at each sweep of the nets.

A peculiar form of taking tunnies is by the madrigue, or, as the Italians call it, tamboro. This is more complicated engine, and somehow expensive to set up. It consists of a series of long and deep nets fixed vertically by corks at their upper edges, and with lead and stones at the bottom. These are kept in a particular position by anchors, so as to form an inclosure parallel to the coast, sometimes extending an Italian mile in length: this is divided into several chambers by nets placed in a zigzag manner opening on the land side. The tunnies, which in their progress proceed along the coast, pass between the tamboro; when arrived at the end, they are stopped by one of the cross nets, which closes the passage against them, and obliges them to enter the tamboro by the opening that is left for them. When once in, they are driven by various means from chamber to chamber to the last, which is called the chamber of death. Here a strong net, placed horizontally, that can be raised at pleasure, brings the tunnies to the surface, and the work of destruction commences. Sailors who have come off in boats for the purpose, give unequal battle on all sides, striking the tunnies with poles and hurling them back, while the chosen enemies, which attracts a great number of curious people to witness it, is one of the great amusements of rich Sicilians, and at the same time one of the most considerable branches of the commerce of the island. When Louis de Lavradores, the celebrated English sailor, he was invited to a funny-fishing at the principal madrigue of Morgion; and found the diversion so much to his taste, that he often said it was the pleasantest day he had spent in his whole profession, although he had spent it in the British Channel.

The tuna is occasionally taken in the British seas, but it can scarcely be regarded as more than a straggler. In the seas of the South of Europe, and especially in the Mediterranean, it is very abundant.

The Bonito (Scopner pelamys) of Linnæus, is also an occasional visitor to the coasts of England, but its true realm is in the tropics. It is a very beautiful fish of a fine blue colour, with four dark lines extending from the pectorals along the side of the belly to the tail. It rarely exceeds thirty inches in length. The Bonito of the Mediterranean, a fish of equal beauty, is a distinct species, and is the Pelamys Sarda of Cuvier. Its back and sides are marked by dark oblique transverse bands. It has much stronger teeth than the Bonito of the tropics.

TICANUBA, a genus of insects, with six legs and podulous organs of motion on their sides, or, at the extremity of the abdomen. They undergo no metamorphosis. They have been grouped by Latreille under two families, of which Lepisma and Podura, two Linnæan genera, are the respective types. As we have a number of species of Indians, covered with small scales, which are used as tests for the powers of microscope glasses. They have long setaceous many-pointed antennæ, distinct palpi to the mouth, and movable false feet on the sides of the abdomen; the body is terminated by articulated acts, three of which are especially conspicuous. The Podurella have four-pointed antennæ, indistinct palpi, an abdomen terminated by a forked tail, which is folded under the belly when the animal is at rest, and serves to aid it in leaping. They are little, long, soft insects. The Lepismana and Podurella live chiefly among wood or under stones.

TICOREA, a genus of plants belonging to the natural order Rutaceae. It has a small 5-toothed calyx, a monopetalous funel-shaped corolla with a long tube, and a 6-crested limb, either equal or unequal. The stamens are from 3 to 5, of which from 2 to 6 are often sterile. The disk is cup-shaped, surrounding the ovary; the stigma 5-lobed. T. jasminiflora is a shrub from seven to eight feet high, a native of Rio Janeiro. The leaves are vernace and stalked; the flowers are white and carmine, on the base, acuminate, obtuse, deep green with pellucid dots. The calyx is rather downy, the corolla white, downy, glandular with pellucid dots. A decoction of the leaves is dangerous for some diseases, and for those of the skin. T. pyriformis differs but little in its character from the last species, but in its stem being generally arborescent, its panicles contracted, its flowers not more than half the size, the bracts more numerous and foliaceous, and the style more prostrated. The
The Report is accompanied by Minutes of Evidence, an appendix of matters relating to the inquiry, and by plans of the rivers Clyde and Tay, Birmingham Harbour and the river Blyth, Harwich Harbour, and Rye Harbour.

The Second Report of the Commissioners is dated March 20, 1846. It is printed separately, as well as with the Minutes of Evidence, the whole forming a very bulky volume, with numerous plates.

The Commissioners state that a more extended inquiry has fully confirmed the views which the limited examination of the previous year led them to. They find that there is not only a general want of control over the management and revenue of the ports, but that such control, in every one of the numerous cases which came before them, would have been the means of saving unnecessary outlay, of preventing encroachments upon the public interests and work, now scarcely remedied, and of preventing the execution of works which it is now expedient to demolish.

The income of the various ports of the United Kingdom considerably exceeds 800,000l. a year, the whole of which is yielded by charters and acts of Parliament, or otherwise, from dues on shipping and on goods borne by shipping; but over the expenditure of which Parliament has not at present the slightest control. After explaining the causes of the misappliance of much of this money, the Commissioners detail their proceedings since the First Report.

They state that they have examined the chief ports on the east coast of England from the river Thames to the Tyne; the south coast from the Thames to the Solent; the coast of Northumberland, the Tyne, the Wear, the Tweed, the Tyne, Berwick, the Wear, Yarmouth, the Wash, Blackney, and the ports of the Island of Man; that in Ireland they have visited most of the ports and fishing-piers around the coast, and have been strongly impressed by the abuse of the public revenue, the inefficiency of the management, and the capacity, and the extent and capability of improvement of its fisheries, which, even in their present state, with the fishery-piers often in ruin from neglect, afford employment to cheap vessels and boats, and 30,000 hands, from door to door. The Commissioners next point out in detail the injuries which have arisen, partly from neglect and partly from mismanagement, and which an efficient control would have prevented; such as the mismanagement of the docks of Dublin, Waterford, Wexford, Cork, Limerick, Galway, Sligo, Londonderry, Belfast, Newry, Dundalk, and Drogheda. They point out the damage which several of the breakwaters have suffered owing to bad construction, and the distress which has been occasioned by the neglect of repairing many of the fishing-piers. They cite as instances of neglect the injury done to Bantry Harbour, Skerries, and Larne, by discharging ballast and stones into them.

After advertizing to the necessity for additional lights and beacons on the Isle of Man, they proceed to animadvert on the rivers and harbours of England. On the north-west coast of England, they examine the River Mersey, the River Mersey, the River Ribble and port of Preston, the river Dee and port of Chester; on the south coast, Salcombe, Dartmouth, and Exeter; on the north-east coast, the river Tyne at Newcastle, the Wear at Sunderland, Hartlepool, Stockton-on-Tees, Whitby, Scarborough, Bridlington, Kingston-upon-Hull, Grimsby, Great Yarmouth, Norwich, Lowestoft, Decies on the Waveney, Bloxneky and Clew on the north coast of Norfolk, Wells, near Blakeney, and Harwich Harbour.

It appears, from Parliamentary Returns, that the aggregate debt of the several ports of the United Kingdom, exclusive of docks in the port of London, exceeds 4,000,000l., and that consequently one-fourth of the whole harbour-income of 800,000l. must be annually appropriated to pay the interest of this debt. This large sum, though borrowed with the sanction of the legislature, has been entirely laid out by the several local boards without the least parliamentary or other special control.

The Commissioners then animadvert on the obstruction and shows which so seriously impede and endanger the navigation of the Thames between London Bridge and Gravesend, arising from neglect occasioned by the conflicting claims of the Admiralty, the Trinity House, and the corporation of the city of London. They also urge the necessity of establishing a Board of Conservancy for the superintendence and control of the management of all the tide harbours of the United Kingdom. The proceedings of the Harbours of Refuge Commission are briefly stated under Refuge Harbour, of P. C. S. (Tidal Harbours Commission—First and Second Reports, 1844, 1846.)

TIDES. [Acceleration and Retardation of Tides, P. C. S.]

TIDES AND PAVEMENTS. The subject of tessellated pavements being already partially treated of under Mosaic, P. C. S., p. 247, the principal object of this article is to notice some recent improvements by which the revival of this elegant and durable kind of architectural decoration has been facilitated. In doing so we may refer our readers for fuller information to the literary portion of a beautifully illustrated thin folio volume published in 1842 by Mr. Blashfield, a gentleman who has done much for the promotion of this branch of art, under the title of 'Designs for Mosaic and Tessellated Pavements, by Owen Jones, architect; with an Essay on their Materials and Structure, by F. O. Ward;' or, for a pretty full popular notice of the subject of ornamental pavements generally, to the 'Pictorial Gallery of Arts,' vol. i. pp. 182, 183.

Decorated paving tiles of baked pottery, commonly called encaustic tiles, which were much used in the pavements of churches and other ecclesiastical buildings of early date, have been recently brought into use again with excellent effect in the Templo Church, London, and many other buildings; and improvements in their manufacture introduced by Messrs. Carey, Chamberlain, of Worcester, and Mr. Minton, of Stoke-upon-Trent, have, by the aid of great pressure, rendered them much harder and less porous than old tiles of the same character, and therefore even more durable. The process of making these tiles is called the 'Japanese method,' because the mosaic work, tessellated tiles, as practised at the Royal Porcelain Works at Worcester, is described by an eye-witness in No. 700 of the 'Penny Magazine,' from which we copy the following curious details: 'The clay, and, if need be, more, differently coloured clays, are imbodied in the other. The body of the tile, which is about an inch thick, is moulded in stiff clay, of the quality required to form the ground colour of the design which is to be printed on the tile: it is then baked, as before, in a mould which, in addition to giving the tile its required form, produces depressions about a quarter of an inch deep wherever another coloured clay is required; the process being repeated under pressure, and baked, in the same manner and screw. The second coloured clay, which, instead of being made stiff like the first, is mixed to about the consistency of honey, is then applied so as to fill all the depressions or cavities, it being carefully plastered in with a knife or trowel. Much care and skill are necessary in the selection of the clays, that they may be of such quality as to contract together in baking as if they were one, although they are of such different consistency when moulded. In order better to guard against injury from irregular shrinking, the tiles are laid aside for about eight weeks to dry slowly, after which the surface is scraped to remove all that may be superfluous of the softer or second clay. The tiles are next covered with bitumen and then baked, and they are then baked or burnt in a similar manner to porcelain. Like porcelain also, they may be subsequently coated upon the upper surface with a liquid glaze, which is afterwards fired; and vitrified, and the designs being afterwards engrailed or incised with a pointed tool, and the cavities are filled with another clay, which is then covered with another glaze, and the whole, so many times repeated, is imbedded in cement, and such holes or other cavities may be formed in their lower surface as will, by affording increased hold for the cement, render it almost impossible to disturb them from their bed.

Among other recently invented methods of imitating the antient Roman tessellated pavements, which are so called from being composed of small pieces termed tesserae or tessellae ('Tessera,' P. C. S., p. 246), Mr. Ward, in the Essay referred to, notices a patent obtained early in the present century, by Mr. C. Wyatt, for producing ornamental pavements by inlaying stone or coloured cement, with the further that these and pavements formed by a combination of cement with terracotta appear to have failed from the unequal hardness of the materials used. More recently, according to this writer, Mr. Blashfield has constructed second or pseudo-pavements very well for indoor purposes, though they would not bear exposure to weather, of cement moulded with metallic oxides; and, but with less success, he has tried bitumen coloured in like manner. In 1829 a patent was taken out by Alfred Snider and Henry Peter for a method of forming tesserae of pottery or porcelain by cutting them out of sheets of clay, and, after baking, combining them into slabs suitable for laying up in the form of Roman cement, of which a complete layer is formed at the back of the tessera. This plan has been followed, among other places, in a large pavement in the saloon of the Reform Club-house. Under ordinary circumstances it is proposed to
form the tesselate, which may be of any required colour, about an inch square, and to combine them into slabs of about eighteen inches square before laying down. In 1840 Mr. Proser, of Birmingham, obtained a patent for a method of producing a substance similar to, but very much harder and less porous than common porcelain, by subjecting a mixture of powdered felspar or flint and fine clay, in dry a state as possible, under great pressure between flat surfaces, so as to condense the powder into about one-fourth of its natural bulk, and then baking it. This process was first applied to the manufacture of a kind of button which has in a great measure superseded the mother-of-pearl; being, when well made, beautiful in appearance, and cheaper and far more durable than common buttons. Mr. Blashfield perceived the peculiar fitness of this process for making tesselate for pavements, and the manufacture has been commenced by Mr. Minton with every prospect of success. These compressed tesselae are made by a simple but powerful machine, which condenses the material to a thickness of about an inch and one-eighth to three-tenths of an inch, and are then baked in an oven; and it was stated by Mr. Blashfield in an explanatory lecture before the Society of Arts (reported in the Athenaeum of 1843, p. 266), that they had been found to bear a pressure of forty tons, and to be proof against injury by frost, some having been tried by plunging them in boiling water and immediately exposing them to a freezing temperature.

Blue and petroleum tesselae are impregnated by metallic oxides during the baking process; but other colours are mixed with the materials before submitting them to pressure. By this process tesselae are produced of such perfect uniformity in size and shape, that when fitted together they unite much more perfectly than those used in ancient pavements, in which the beauty is often impaired by broad and irregular lines of cement. In constructing pavements with them, the tesserae are arranged, face downwardwards, upon a smooth level surface, and, when a convenient portion of the design has been thus adjusted, a stratum of Roman cement is laid upon the back, and worked into the joints. Such cemented slabs thus produced are laid down upon the prepared foundation in the same manner as already described in the case of Singer's plan. This mode of producing tessellated pavements possesses many advantages over the ancient plan, in which, a level foundation having been prepared by crumpling stones together, or forming a thick floor of succo or concrete, a layer of plaster was spread to receive the tesselae, which were laid one by one while the plaster continued soft. This method required much time and care to preserve the level, and that as could not be done perfectly, much additional labour was involved in the subsequent rubbing down and polishing of the surface, an operation which, in the case of Singer's plan, would have been entirely obviated by destroying their hard surface. Owing to the imperfect fitting of the ancient tesserae it was also necessary to spread cement upon the surface of the pavement, in order to fill up the joints and crevices, and afterwards to scrape it off again.

By Proser's process, with the power supplied by an hydraulic press, bricks and other larger articles may be produced, among which may be mentioned slabs, inlaid with coloured devices, for chimney-pieces and other architectural decorations.

An extensive collection of specimens of Roman tessellated pavements, in a very large atlas folio, published by William Fowler early in the present century, together with specimens of ancient stained glass, is worthy of the attention of those engaged in the revival of this elegant species of decoration, which, though necessarily expensive, has been so much reduced in cost by the introduction of the compressed tesselae, that in some cases they have superseded the use of oil-cloth in the construction of the building, substitution being made on the score of economy, although sanctioned by a refined taste.

**TIMBER, PRESERVATION OF.** Whatever causes may combine to promote the decomposition of wood by fungus, whether the result of fermentation or of a mechanical process, it must be remembered that there can be no doubt that imperfect seasoning, by leaving in the pores of the timber a large portion of the fermentable juices always found in recently-felled timber, is one of the most damaging influences, and therefore that everything in promoting the durability of wood as it is in lessening the tendency to those changes of form and hue which so greatly increase the difficulties of the carpenter and joiner. The process usually consists in the exposure of the timber to the action of air in dry situations, ice, locks or piles so constructed as to allow the free circulation of air in contact with as much as possible of the surface of each piece of timber, until the sap or vegetable juices shall have been driven off, and the wood hardened, that the action of the microscopic fungi which constitute various kinds of rot, in order to the success of this operation it is important that the pile of timber be so far elevated from the ground as to allow the air to circulate freely around it; and also that, if exposure to rain be not entirely avoided, care be taken to prevent the lodgment of moisture in any place where it would be likely to remain in any place. Great advantages have been derived from methods of heating the wood which has been reduced to thin boards and put into boxes, or even solid blocks, and afterwards introduced in our dockyards, in the stacking of timber upon elevated supports of iron or stone, and the building of ships beneath spacious roofs, which protect their timbers from rain, while they allow the air to circulate around them.

In the article House, pp. 53 and 54 of this volume, we have noticed a very simple, though not unimportant, improvement upon the common method of seasoning flooring-boards. Kiln- drying, and the expulsion of sap by charring or scoring the surface of the timber, have also been tried, but without success, as substitutes for the tedious operation of natural seasoning.

Another process, which may seem at first sight very unlikely to succeed, and respecting which indeed the most contradictory opinions are given by writers on the subject, consists in the use of the fermentable juices, for the preservation of timber, by lengthened immersion in fresh or sea water, and subsequent drying. Immersion in sea-water especially has been extensively practised of late years; and it is stated that many splendid buildings of the ancient mariners have been preserved, some writers having attributed the durability of the materials to their use. In some cases, this treatment has arrested it, the action of the sea-water appearing to destroy the vitality of the fungi. Some authorities however state that ships built of timber which has been so immersed, are unhealthy in consequence of the hygroscopic properties acquired by the absorption of salt.

The protecting power of metallic oxides, when applied to the surface of wood in the form of paint, is well known; and many abortive schemes for the preservation of timber have been devised to act upon the same principle, which is that of excluding such external influences as might promote decay. To imperfectly seasoned timber however such applications are worse than useless, because by filling up the pores they impede the natural drying of the vegetable juices, and therefore rather promote than check internal decay. Far more efficient than these are the numerous modes of protection which involve the impregnation of the wood with some antiseptic substance, or with such matters as, by pre-occupying the pores, may render the reception and germination of destructive fungi mechanically impossible. Historical notices of the different combinations of substances used in the "Mechanic's Magazine," vol. xxxix. pp. 340-350, extended from a report made in 1843 by a committee of the Franklin Institute, on the best method of paving highways; and in a previous number of the same work (p. 225) is a report of an interesting conversation on the subject, at a meeting of the Institute of Civil Engineers, in 1842, when several of the principal modern inventions were discussed.

Of plans for protecting timber by impregnation there has none that attained such general celebrity as Mr. Kyran's, which was patented in 1832, and has been very extensively practised under licences granted by the Anti-Dry-Rot Company. The preservative agent in this process is chlorides of mercury, commonly called corrosive sublimate, which is dissolved in water, and forced into the pores of the timber, in closed tanks, by means of force-pumps, and which combines with the alumines of the wood, and converts it into a compound capable of resisting the ordinary chemical changes of vegetable matter. The idea of using corrosive sublimate for this purpose does not appear to have originated with Mr. Kyran; for the same substance having been tried and recommended as an anti-dry-rot application by Sir Humphry Davy many years previously. The alleged failure of the precipitate formed by Kyranisation to timber when exposed to the action of sea-water, has led Sir William Henry, a Commissioner in the navy, to patent a method for preserving timber by impregnation with chloride of zinc, which process, like Kyran's, is also applicable to canvas, cordage, &c., and to which the name of Anti-Dry-Rot has been applied, and which is recommended the application of cresote, obtained from the distillation of tar, and applied in the form of gas, by which it may be made to penetrate to the heart of the largest logs. This treatment renders the wood exceedingly hard, so much
so indeed as to render it difficult to work. An oil extracted from
chips and refuse wood was used for the same purpose by
Mr. Macconachie in 1803. He applied it by placing the tim-
ber on a frame, fanning it with air and fumes from the
pores of the timber by the admission and subsequent con-
densation of steam; and, after repeating this process as often
as needful, plunging the timber into the oil, which filled the
exhausted pores, hardening out the sap and gums, forcing
heated fluids into the pores by hydrostatic pres-
sure. Dr. Ure mentions the application by this process of
oil of tar and other bituminous matters containing creosote,
and remarks on the inutility of the process when it was
attempted for rendering insensible to water, or soluble in
water, or in alcohol; in animals it may be either soluble or insoluble in water. For the mode of obtaining it
see COSMOPOLITANS, P. C. S., p. 349. It is one of the substances
directly prepared from the union of the
youngest roots; whether it is only formed there, and afterwards
conveyed to the other parts, or whether it is produced in any
other part of the plant, is uncertain. Its property of being
readily soluble in water facilitates its transference to the
various organs. It may however assume the solid state and
become deposited in cells; in this form it occurs in many
seeds, occasionally being their principal constituent. This
deposition is effected in a very simple manner. Most acids
render it insoluble, and therefore the mere presence of an acid
is usually sufficient to accomplish the transformation: again,
the insoluble protein may be redisolved by alkalis, and
hence, after it has been deposited in the cells in a solid state, it
may be removed to another part of the plant through the
medium of an alkaline solution.

Whether protein can be formed within the animal body is
uncertain, but it cannot be doubted that the protein
compounds in vegetables are imparted to animals in their food, and as these compounds form the principal component parts of the
animal body, this ingredient must be supplied either wholly or in part by plants.

The protein-compounds existing in plants were till quite
recently known as soluble albumen, coagulated albumen,
and gelatin. Ludlow in 1844, and Liebig in 1845, proposed
three names for the vegetable albumen, vegetable fibrin, and
gelatin, asserting that they are identical in their
physical properties and in their chemical compositions with
the corresponding principles in the animal kingdom. Multip-
le, however, the discoverer of these animal substances, denies the accuracy of this statement.
'The special character of these animal substances is,' he remarks, 'determined by the small portions of sulphur and phosphorus they contain, by which they differ from each other
and from pure protein. The proportions of sulphur and
phosphorus in the three vegetable substances are still unknown;
and therefore the names proposed by Liebig cannot be applied
wholly to both vegetable and animal substances.

Moreover, both vegetable and animal substances differ so much from animal fibrin and casein, both in form and appearance, that they ought not to have a similar name.' We
shall retain the former names, representing by leysin the
substance which is precipitated in white flakes, when the infusion
of crushed peas or beans in warm water is mixed with an
acid.

By soluble vegetable albumen we mean to designate that
substance which, being soluble in water, is precipitated from
the juices of plants by heat, alcohol, or acids. It is soluble
in weak alkaline fluids, from which it is precipitated by acids,
and, independently of the sulphur and phosphorus, has
nothing in common with the vegetable albumen of the
same composition. We have, however, for convenience,
chosen the term albumen we mean the compound of protein, sulphur, and
phosphorus which is insoluble in water; it exists in the
seeds of the cereals, in almonds, &c. By gelatin we understand
the substance which can exist either as a gelatinous

P. C. S., No. 165.
ordinary gluten obtained by washing away the starch from flour. It is the same substance as is described in the article Chemistry, P. C. S., as glutenine. Its composition according to Mulder is 
\[ (C_{66}H_{54}O_{34}) + S + 10 \text{Fr} + S_i \text{if we take Fr as an arbitrary symbol for protein;} \]
and sufficient to indicate that it consists of 10 parts of protein, one part of sulphur, and 18 parts of phosphorus.

It is a substance, which possesses the property of dissolving the protein-compounds, and the question whether Mulder or Enderlin be correct is still undecided.

A new alkaline solution of protein by an acid, its solubility is greatly diminished; a fact which Mulder regards as elucidating the properties of other substances. The sulphurous and phosphoric acids for instance possess the property of dissolving the blood corpuscles; and, on the contrary, by which protein is readily dissolved, is destitute of that property. Very dilute hydrochloric acid occurs in the stomach, but it possesses the property of dissolving protein, it is powerless the food (at least the portion consisting of protein-compounds) tender, and assists digestion. Some acids enter into combination with the protein-compounds, producing comparatively insoluble bodies. For this reason certain vegetable products, the asparagines are very efficaciously employed in putrid fevers, scurvy, &c. As an illustration of the combination of the protein-compounds with salts, we may notice that of bone-earth with casein. Bone-earth is a phosphat of lime, what bone-earth is represented by the formula 3 P O. + 8 Ca O. In casein, and therefore in milk, it exists in great quantity, and this seems to supply a large amount of earthy matter to the tender bones of young animals.

In addition to albumen and fibrin, a third protein-compound exists in the blood, constituting the cell-wall of the corpuscles. It is termed globulin. Its real composition is unknown: Simon regards it as casein. All these protein-compounds contain more or less phosphat of lime, which thus finds its way to the bone.

Two other very important protein-compounds exist in the animal body, namely the albumin and trioseid of protein. They both exist to a large amount in the blood in inflammatory diseases, and to a small amount in healthy blood. The latter is soluble in water, the former is not. (For the mode of obtaining them in a state of purity, and for the fullest account of them in the English language, we must refer to Dr. Day's Introduction to Simon's Animal Chemistry, published by the Sydenham Society, London 1845.) At every recovery of the small amount of them in the blood, and Mulder (who must be regarded as the highest in authority in all that relates to protein) believes that they form around the blood-corpuscles a thin layer having the same composition as the albumen and fibrin.

The above sketch is sufficient for our purposes at present. In a later part of this article we shall have occasion to return to the protein-compounds. We now turn to the second group, commencing with the consideration of cellulose, or the cellular substance of plants. As the morphology of this substance has been fully discussed in the article Tissues, Vegetables, we shall confine our observations to the chemical characters and metamorphoses of this substance.

This cellular substance may be prepared from all the parts of plants without exception, by dissolving (by certain reagents) the other substances associated with it. Pure cellulose is easily obtained from the pith of the elder-tree, or from the stalks of some plants. It is a substance which is starch, gum, fats, resins, vegetable alkalises, salts, sugar, and the peculiar woody matter termed by Payen matière insatiable. After the removal of these substances by extracting with alcohol, ether, nitric acid, and water, the cellulose, which was previously solid and dens, assumes a spongy appearance. As a proof of its constant composition, it is worthy of mention that the following substances, previously purified in this manner, have similar results, viz. the ovula of almonds, of apples, of the Helianthus annuus, the sap of cucumbers, the tissue of the cucumber, the pith of the elder-tree, the pith of the Zelkovenose pellenus, cottonwood, the leaves of endive and of the Acanthus glandul.osus, the tracheen of the Mussa sapontum, films from the path of oak-trees, from Mulder's laboratory that sulphuric acid or dissolve will convert cellulose into dextrin. Hence the cellulose substance is closely allied to starch, dextrin, and amylose, and containing their products in the vegetable kingdom, and no doubt being itself produced from one of them, namely from dextrin. It is therefore of great importance to the animal body. It explains the nourishing power of those plants in which the incorporation of the cellulose is prevented by artificial means, as of Greeks, endive, sea-kale, &c. The cellulose of these plants, being easily converted into dextrin, may be reckoned amongst the substances which are most serviceable in maintaining the vital functions of animals.

Further, as cellulose exists ready formed in the youngest parts of plants, it belongs, together with proteins, to the first formation of vegetable matter; thus starches, gums, &c., which consist for the most part of cellulose. In many fruits containing a large proportion of cellulose, there is much sugar. These different substances may be produced from the same cellulose, simply by a change in its physical character and a new chemical arrangement of its constituents. On the other hand, we observe that fruits, from being sugary, become mealy when kept through the winter; this being a converse change of sugar into cellulose. Hence, as Mulder remarks, 'we may consider the cellular plants as consisting chiefly of cellulose and of protein-compounds; the vascular plants containing, in addition, the incrusting or real woody matter. In the same way that the cells of the animal kingdom consist of the composition of plants; they are found everywhere and in all their organs. Cellulose is to plants what gelatin is to animals; they form together the cells in these two kingdoms. In the cells is the principle of the animal proteins, and in the tissues the composition of plants. These are the indispensible constituents of plants; they are found everywhere and in all their organs.'
lead us to infer that cellulose can often be modified as it were into starch, though still retaining the appearance of cellular membrane. The similarity of the chemical constitution of the two substances renders their conversion apparently easy.

For 1 eq. cellulose (C_{6}H_{10}O_{5}) = 2 eq. starch (C_{6}H_{12}O_{6}) + 1 eq. water (H_{2}O). Hence, by a separation of the starches of barley in the dry state and the starch may be converted into starch; and conversely, by the absorption of water, starch may be converted into cellulose.

Starch exists in three separate forms: common starch, dextrin, and cellulose. The first is interchanged between dextrin and cellulose; the second, between dextrin and common starch; and the third, between common starch and sugar.

Starch occurs in the form of globulose, which are found in the most different parts of plants, and present varying forms in consequence of having to adapt themselves to the shape of the cells in which they have been deposited. It has been frequently observed that starch-globules, after being dissolved, again disappear under the influence of growth; that is to say, they become dissolved and carried away to other parts by the sap, and give origin to new products. In young parts of plants, such as the extremities of the radicle, no starch is present, but only cellulose and protein-compounds; hence, it is not formed till after the parts in which it has to be deposited have obtained a certain growth. Payne could not detect any starch-globules in dissolving substances in the case of dextrin caras; hence, if starch is present, it must occur in a dissolved state, or in a modified or changed condition. It is further worthy of remark, that in those bulbs in whose scales there is much starch, the dextrin is far more susceptible of undergoing the changes in water than in those where it is comparatively slight; that is to say, it becomes converted into other substances. This is the reason why much less starch is to be found in the parts of a plant which are above-ground than in the roots; and that in plants whose stalks contain starch it is found chiefly in the pith. We have already mentioned that starch-globules may be dissolved wholly or in part during the growth of the plant. According to Payne the products of this metamorphosis are dextrin and sugar, and the cause of the action dextrin, a substance the effect of which on starch separated from plants is now well known. This is the change which freezes potatoes undergo when all the starch is converted into sugar. It also takes place in the growth of new potato-plants; all the starch disappearing from the tuber, and being replaced by sugar. According to De Candolle, the quantity of starch in potatoes increases during their ripening almost in the same degree as it afterwards diminishes. In August, 100 lbs. of potatoes gave 10 lb. of starch; in September, 14-96 lb.; in October, 14-75 lb.; in November, 17 lb.; it remained constant till the end of February; in April it had diminished to 14-78 lb.

There is still considerable mystery regarding the formation of starch. We have undoubted evidence that it gives rise to the formation of dextrin and sugar, and it is just as certain that the dextrin and sugar are first converted into starch. In addition to its uses in forming dextrin and sugar, it is likewise the efficient agent in the production of fat and of chlorophyll.

Lichen-starch. The starch of the cryptogamous plants has been examined by several chemists, especially by Vogel and Dietrich. It is coloured green by iodine, instead of blue, and in several other points differs from ordinary starch.

Inulin is a modification of starch, very abundant in the dahlias, heliunum, and taraxacum, but found also in many other plants. [Chemist', P. C. S., p. 345.] It is very readily converted into sugar, and it combines with this sugar and carries it with it, it is obvious that the ultimate analyses of inulin from different plants must vary. Possessing apparently the same composition as starch, it differs in not being changed into a jelly by hot water; nor does it turn blue with iodine, but yellow. It may as well be termed a variety of sugar insoluble in cold water and destitute of taste, as a variety of common starch. From the facility with which it may be converted into sugar, it is most likely, like dextrin, to be placed among the sugar and common starch. In many plants dextrin is a transition substance from common starch to sugar, as is the case when either sulphuric acid or dextrin [Chemist, P. C. S., p. 324.] is brought into contact with it. It is therefore in the form of starch and sugar, without the formation of dextrin.

As its composition is the same as that of cellulose, it is probably produced from that substance and not from starch.

So situated as to the consideration of the very important constituent of plants, dextrin, which is obtained by treating starch with diastase. [Chemist', P. C. S., p. 345.] Mulder has shown that dextrin may also be obtained from cellulose by sulphuric acid and by diastase. The quantity of diastase required is extremely minute; if much is added or the process continued too long, grape-sugar is produced. It is by those or similar means that nature converts cellulose into dextrin, and dextrin into sugar. As in making bread, starch is converted into sugar by a diastase from a mornings' meal; the same reason why it should not in a similar manner be produced in the growing plant, and convert the cellulose into dextrin.

The sap of nearly all plants contains a certain amount of dextrin, which, having the same chemical composition (C_{6}H_{10}O_{5}) as gum, and in many other points resembling it, has been in most analyses put down as gum. If one equivalent of water (H_{2}O) be taken from one equivalent of cellulose (C_{6}H_{10}O_{5}), two equivalents either of gum or dextrin (2C_{6}H_{10}O_{5}) are formed. Thus a part of the cellular membranes may be converted into dextrin by catalysis [Chemist, P. C. S., p. 341] without destroying the cells, if the vegetable sap, while passing through them, contains only a very minute quantity of diastase, or of a substance resembling it.

We have already mentioned that dextrin does not often have been frequently confounded. The most important difference between them is, that the latter may be changed into grape-sugar by sulphuric acid or diastase, while the former is not. Dextrin belongs to the nutrient matters; all the starch taken as food being converted by the gastric juice into it. The gums are mere excretions, and are apparently of little or no importance in plant part or algae. One of the most important is mentioned by Casseus, and by Marcellus, to which the use of the latter in the formation of cells cannot be doubted.

Dextrin is not merely a source of cellulose, but likewise of starch, sugar, gum, and perhaps other vegetable substances; it is almost as valuable to plants as protein is to animals, for it is a constituent from which their organism derives its most important products. The composition* of dextrin being C_{6}H_{12}O_{6}, the formation of cellulose from dextrin is produced by every two equivalents of dextrin taking up one equivalent of water. Thus

1. C_{6}H_{12}O_{6} + H_{2}O = C_{6}H_{10}O_{5} + CO_{2}.

Starch and gum contain the same elements in the same proportions as dextrin, and hence for their production require merely a re-arrangement of the molecules.

Sugar, as we shall immediately show, requires only the addition or subtraction of one element from the elements of dextrin.

The different species of sugar, as far as they are known, are:

1. Milk-sugar: C_{6}H_{12}O_{6} + 5 H_{2}O.
2. cane-sugar: C_{6}H_{12}O_{6} + 2 H_{2}O.
3. grape-sugar: C_{6}H_{12}O_{6} + 2 H_{2}O.
4. Eucalyptus-sugar: C_{6}H_{12}O_{6} + 9 H_{2}O.

Milk-sugar is an integral compound of the milk of the mammals, and has very rarely been met with anywhere else. It has recently been detected in eggs during the process of incubation; but this observation requires to be confirmed.

Cane-sugar is the most entirely related to starch and dextrin differing from them merely by one equivalent of water. It is not by any means so widely distributed as grape-sugar, being found in very few plants besides the sugar-cane, beet, and sugar-plants. Grape-sugar is identical with the honey in the honey-comb, and in diabeto, urine, and with the glucose or fruit-sugar of the French chemists. The uncrystallizable sugar which is obtained during the decomposition of many plants, and which is yielded by starch and cellulose is also similar to the grape-sugar, or the free-acting sugar, acid, has the same composition as grape-sugar.

Eucalyptus-sugar is a species of manna produced in Van Diemen's Land by various species of eucalyptus. Whether it

* The formula C_{6}H_{12}O_{6} is O in the article Chemist, P. C. S., p. 245, is evidently a mistake. 4 M 2
is the natural sap spontaneously escaping, or whether it is the sap extracted by the locust and afterwards excreted, is uncertain. Investigations have been carefully examined by Professor Johnston of Edinburgh.

There is obviously an intimate connection between these different kinds of sugar, as well as between cellulose, starch, and cane-sugar. They all contain C, H, and O, in combination with the elements of water. As they all contain C, H, or a multiple of it, they are produced from each other by a simple change depending on catalytic force. [CHEMISTRY, P. C. B., p. 541.]

If sulphuric acid is allowed to act on gelatin, a species of sugar containing nitrogen, and termed glycerol or gelatin sugar, is formed. In its formula it is C_3H_6N_2O. It is called gelatin sugar because it is formed in the stomach, and is easily digested. Hence it is subject, when changed into cane-sugar, to the same conditions as cane-sugar when supplied to the body. On these grounds Mulder considers that gelatin-sugar should be classed among the digestible substances. In fact, gelatin is not only an essential substance, but since it has been found to be necessary for the growth of the animal, then sugar, either derived directly from the food or produced from starch in the alimentary canal, may be used for this purpose.

It is not accorded to what part of the plant sugar is formed. Mr. Knight states that birch sap contains more sugar the farther from the root it is collected; this seems to prove that the sap, which probably contains much starch, is changed into sugar and conveyed through the cell-walls. When sugar accumulates in certain parts of a plant, it always almost remains in solution; it is however found crystallized in small few instan cases in the formation of hoarfrost. [CHEMISTRY, P. C. B., p. 541.]

Closely allied in its chemical composition to sugar is a peculiar substance to which the term mucilage is given. Although insoluble in water, it assumes the appearance of a mucilaginous mass when immersed in that fluid. It sometimes accumulates largely in certain parts of plants, as in the perisperm of quince-seed, lime-seed, &c.; it is the chief constituent of the gums tragacanth and bassam, and is abundant in various roots, as for instance the malows. According to Mulder's analysis it must be represented by the formula C_6H_10O_5. It has been shown by Schmidt that mucilage when digested with dilute sulphuric acid is converted into sugars. There is also a link to the following series of analogous substances:

- Grape-sugar and fruit-sugar
- Cellulose and soluble mullin
- Starch, dextrine, inulin, and
- Mucole, mural sugar, and eucalyptus sugar

In its physical characters the product of the mucous membrane of the animal body resembles vegetable mucilage. Owing to its insolubility in water, both these substances serve to cover denuded parts of animals, and thus they are both suited to lessen or prevent the influence of acid matters on the tender parts of the animal frame. It is for this reason that the mucilage of sallow, tragacanth, &c., may be made, in certain circumstances, to supply temporarily the want of animal mucus. In chemical composition they are perfectly distinct, as animal mucus contains nitrogen. The mucus of the animal body seems however to differ according to the organs by which it is produced. [Davy's edition of Simson's Animal Chemistry, vol. ii. p. 78, note.]

We now arrive at a peculiar group, occurring both in the vegetable and animal kingdoms—the fats. Stearin, margin, and olein are the most widely distributed fats in the organic kingdom, but they are not the only ones. They were formerly regarded as salts formed by fatty acids with glycerin [CHEMISTRY, P. C. B., p. 544]; recent investigations have been given that this view requires a slight modification. Berzelius thinks that glycerin does not exist readily formed in the neutral fats, but that it is a product of the formation of soap; and he considers the base of the neutral fats to be the oxide of a radical (C_6H_12) which forms lipoyle. Glycerin is then formed from two equivalents of the fatty acids and three equivalents of water: 2 C_6H_12O_1 + 3 H_2O = 2 C_6H_12O_3 + 3 H_2O. (If to this we add one equivalent of water, we obtain the formula given in CHEMISTRY, P. C. B., p. 544.)

As to this view, which is supported by Redtenbacher, Varrentrapp, and Mulder, the base of every neutral fat yielding glycerin is a compound which is represented by C_6H_12O_3.

The most important of the fatty acids are:

- Stearic acid: C_17H_35O_2 + H_2O
- Margaric acid: C_17H_33O_2 + H_2O

These are universally diffused in plants and animals; and, combined with the oxide of lipoyle (C_6H_12O_3), form the neutral fats—stearin, margin, and olein; and this is the form in which they most commonly occur in the organic kingdom. Sometimes however a more powerful base (potash, soda, &c.) removes the oxide of lipoyle, and there are then formed compounds of the fatty acids with alkalies.

In connection with this subject, Mulder observes that when salad-oil is conveyed into the stomach, it may pass unchanged into human fat, for both consist of margin and olein, although in different proportions; and as margin and olein from salad-oil contain more water, they are more simple than to assume that these substances are directly transferred, without change, into the fats of the animal body.

But if some of these vegetables are eaten by a sheep, the olein and margin are converted into the fatty acids of the animal, since mutton-fat contains a large amount of stearin.

In this case the change is easily understood, for 2 eq. of stearic acid (C_17H_35O_2) = 1 eq. of stearic acid (C_17H_33O_2) + 1 eq. of oxygen. It is found that stearin when treated with stearin in two equivalents from a fatty base is produced, and one equivalent of stearic acid is produced, and one equivalent of oxygen is given off. In all probability, such a decarboxylation of the maragine in the food the sheep is really effected; and on the contrary most of the food may be in the form of fatty acids, and no simple is to assume that these substances are directly transferred, without change, into the fats of the animal body.

Fats are united to form an animal part of their case or fat. In fact the condition of the bile as it enters the duodenum renders it impossible for the fat to enter the blood without undergoing this change. If it is united with the blood, we readily understand how compounds of fatty acids and soda should exist in the blood and in various parts of the body. When a soap-soda however exists in the blood, it cannot form a neutral fat, such as we have seen without combining with glycerin. This leads to the inquiry, in the first place, whether these soap-soda meet with glycerin; and secondly, if they do, whether the glycerin would combine with the soap-soda and form neutral fats. A possible reason for believing that both these questions may be answered in the negative, for the glycerin set free when the soap-soda is formed, is most probably at once decomposed; and further, that the glycerin will not remove the soda from the fatty acid and form a neutral fat.

It has been suggested by Mulder, that although glycerin will not enter into this combination, the oxide of lipoyle in a nascent state may do so, and that in this manner the fatty acids may be converted into neutral fats and deposited in the cellular tissue and other parts of the body. We have already shown that (according to the opinion of Bertelius) glycerin is the oxide of the radical (C_6H_12). The second oxide of this radical exists in lactic acid, which is supposed by the great majority of chemists to be present in most parts of the body. While lactic acid (C_3H_6O_3) is sublimated, we obtain a white sublimable, the composition of which is C_6H_12O_5; while the composition of the oxide of lipoyle is C_6H_12O.

It may happen that there are causes of deoxidation at work in the system, by which some of the substances usually converted into lactic acid are made to produce oxide of lipoyle, which in the nascent state unites with the fatty acids, forming neutral fats.

Hence in all probability the neutral fats are not deposited directly and unchanged in the cellular tissue, but are first saponified, and entering the blood as margarine and oleate of soda, are again reduced to neutral fats by the influence of lactic acid.

In many parts of plants, especially in the perisperm of some fruits, a fatty matter (popularly known as wax) occurs. It has been known to exist in plants, but it has only recently...
been shown that bees can prepare it from honey, which does not contain any wax at all. It is the wax that gives to grapes and other fruits their characteristic sweetness; it abounds in the skins of apples, and is a component of the green colouring matter of leaves (chlorophyll), of which we shall presently speak. Aréquin has analyzed the crystalline wax which collects in front of the mouth of the bee, and he has given the name ceresina. He mentions an important peculiarity in connexion with it, namely, that those kinds of sugar which bees have collected into wax when reversed, whereas with the reverse, whereas with the bees, which contain much ceresina but little sugar. From this we should infer, that either wax is used in the plant to produce sugar, or to form wax. This would account for the fact that in the following experiments of Gundach. He fed bees with a solution of sugar-candy in water, and saw them producing wax. Thus the sugar-cane and bees are both enabled to convert sugar into wax, that is, into a fatty matter.

There are some animals, just as there are some plants, which contain peculiar fats; there are even separate organs in which certain fats are formed.

In butter we find the following acids, chiefly in combination with oxides of lipoyle: margaric and oleic acids, and

<table>

Butyric acid is occasionally present in the urine, the gastric juices, and the sweat; the others occur only in butter.

From the manner in which the plant is separated in the liver of the Phytother macrocephalus; phosphoin, in the fat of Delphina phocena; cholestearin, ambranin, in amber; and the brain-fats known as oleocaprol, cerebrof, cephalol, and steareol are illustrations of this class.

It is worthy of observation, that both in the vegetable and the animal kingdom there seems a connexion between the protein-compounds and fat: when we find solid protein-compounds, which we often find at the same time a large quantity of fat, as in numerous seeds; the brain and milk serve as illustrations of the same point in the animal kingdom.

The next question for our consideration is the formation of fat—a subject which has given rise to much angry and interminable discussion between the leading chemists of France and Germany. Dumas, who was acquainted with the representatives of the French school, maintains that all the fat of animals originates in and is obtained from plants; while Liebig, on the contrary, maintains that a portion of it is formed by the animal itself, from starch, sugar, and gum. The goose was the animal respecting which the dispute originated. When fattened with Indian corn, the starch must, according to Liebig, have been changed into fat, because he had found at one time a quantity (about 1½ pounds) of starch in that kind of grain. Dumas however extracted 9 per cent. of fat from Indian corn (or ninety times as much as Liebig), and thus he found in the food which the goose had eaten much more fat than could be accounted for. The actual fact is, that the amount of fat in this grain is so variable that no conclusion can be drawn from the experiment. Liebig quotes many examples of substances which, although they contain little fat, are well known by experience to be especially fit for fattening the animal body. Rice, peas, beans, and potatoes are all known to possess this property; yet rice gives only 0·2 to 0·8 per cent. of matters soluble in ether (the ordinary means of determining the amount of fat); peas 1·2 to 2·6; beans 0·7 to 0·8, and dried potatoes 0·35 per cent. Thus any animal that has eaten 1000 pounds of one of these substances may obtain from them 2 to 8, 12 to 21, 7, or 8½ pounds of fat respectively. He makes the following calculations—

Three pigs to be fattened in thirteen weeks require 1000 pounds of peas, and 6925 pounds of boiled potatoes, the latter being equal to 1590 pounds of dry potatoes. These contain in all 26 pounds of starch yielding 31, and the potatoes 5 pounds. One fattened pig gives on an average 50 to 65 pounds of fat, the three yielding 150 to 165 pounds. Each pig before fattening contains on an average 18·5 pounds of fat—that is, 54 pounds for the three. If these 54 pounds be added 26 pounds contained in the food, we get 80 pounds; and if we subtract these from 150 to 165 pounds, there is a remainder of 70 to 90 pounds, from the starch, &c., of the food.

Leibig’s opinion is further strengthened by the circumstance that some fats are undoubtedly produced in the body, as, for instance, the fats peculiar to the brain, cholostearin, cetin, pholesterol, &c. To obtain these from other fats requires just as much a new arrangement as if they were produced in the body; hence, in a scientific point of view, there is nothing improbable in the supposition that animals are able to produce fats.

With regard to the formation of fat in plants, it is worthy of observation that all fats which yield oil on pressure—as the castor-oil seed, hemp seed, &c.—contain starch in their early stages, this starch disappearing as the oil increases, and when the seed is completely developed is a trace of the starch remaining. This renders it probable that these fatty matters are formed from starch. From their ultimate composition it is obvious that whenever fats are produced from any substance these are fatty acids or highly oxidised compounds, or else that oxygen must be itself liberated. Liebig observes that if from the formula for starch, C₅H₇O₂, we take 9 equivalents of oxygen, there will remain in 100 parts—

<table>
<thead>
<tr>
<th>Element</th>
<th>Mass</th>
<th>Equivalent</th>
</tr>
</thead>
<tbody>
<tr>
<td>C</td>
<td>70</td>
<td>70</td>
</tr>
<tr>
<td>H</td>
<td>70</td>
<td>7</td>
</tr>
<tr>
<td>O</td>
<td>9</td>
<td>9</td>
</tr>
</tbody>
</table>

The empirical formula for fat which comes nearest to this is C₅H₇O₂, which gives in 100 parts—

<table>
<thead>
<tr>
<th>Element</th>
<th>Mass</th>
<th>Equivalent</th>
</tr>
</thead>
<tbody>
<tr>
<td>C</td>
<td>79-4</td>
<td>79-4</td>
</tr>
<tr>
<td>H</td>
<td>10-8</td>
<td>10-8</td>
</tr>
<tr>
<td>O</td>
<td>9-8</td>
<td>9-8</td>
</tr>
</tbody>
</table>

According to this formula an equivalent of starch, in order to be converted into fat, would lose one equivalent of carbonic acid and seven of oxygen, or (expressed in symbols) C₅H₇O₂ = C₅H₇O₂ + 4 + 7 O.

The same point is also clearly shown by contrasting the ultimate composition of starch and fat.

<table>

</tr>
</tbody>
</table>

As we are not acquainted with any constituent of plants which can take up the oxygen thus liberated in the formation of fat, we must regard this as one of the sources of the oxygen given off by plants. Mulder has given the following scheme as an illustrative of the mode in which starch may possibly be converted into fat or oil, in the vegetable kingdom:

Making as before 84 78 78

There is a substance almost universally diffused throughout plants, which we must here notice, and that is the green colouring matter of the leaves, called plant-mass or chlorophyll. For the following account of this substance we are almost entirely indebted to the investigations of Mulder. It is a striking fact that young leaves have a much lighter green colour than those which are older, showing that the quantity of chlorophyll increases with the age of the leaves. If chlorophyll were a substance poor in oxygen, and were derived from substances rich in oxygen, this fact alone would be sufficient to explain the power which the green parts possess of separating oxygen. This however is not the case; chlorophyll is rich in oxygen. Nevertheless the leaves give off oxygen not because they are green, but while they are becoming green.

When green leaves are digested with ether the liquid becomes green. On evaporating the ethereal solution, and treating the residue with hot alcohol, a considerable amount of white fatty matter (wax) separates on cooling, while the green colouring matter remains in solution. Before proceeding to the consideration of the green colouring matter, it will be expedient to say a few words respecting the mixture it forms with the wax.

In a physiological or botanical sense this mixture has the name of chlorophyll; in a chemical sense the term is restricted to the actual green pigment. To prevent confusion the former is designated as C. chlorophyll; B. indicating the botanical, and C. the chemical signification of the word.
We find similar mixtures of a waxy fat, and colouring matter, in other external parts besides the leaves, namely in the stems especially of such coloured; and when digesting them in ether we obtain a large quantity of waxy matter in solution, varying in tint according to the colour of the skin; being gray when obtained from apples, and of a beautiful orange colour when obtained from the berries of the mountain ash.

The degree in which the action of light contributes to the change of colour in the C. chlorophylle which exists in the leaves, is sufficiently exhibited in the production from the colouring matter of the skin of ripe fruits may be obviously inferred from the green colour which such fruits retain if they do not receive a sufficient supply of solar light, or from the difference of colour produced in the opposite sides of B. chaise fruits, as well as from the fact that leaves when deprived of the action of light become colourless, while if completely exposed to its action they secrete a considerable amount of B. chlorophylle.

This apparent anomaly in the action of light on the skins of fruits and on leaves is dependent on the same cause as the change of colour in the leaves during autumn: namely, that light can only produce B. chlorophylle when there is a sufficient supply of materials for its renewed formation as often as the existing quantity is decomposed by the influence of the light; and that as soon as this supply is exhausted the green colouring matter is itself decomposed, and other compounds are formed from it.

Light acts powerfully in keeping plants green, and likewise exerts a powerful decomposing action upon all colouring matter in the plant. B. chlorophylle not excepted; thus asparagus, potatoes, young leaves, &c., become green whenever they are exposed to light, and hence there must be a substance widely diffused through plants, which causes the production of chlorophyle or that spot does not maintain a constant colour beneath it as far as light can penetrate through the semi-transparent parts. All plants however are not coloured green; some have no colour at all, while others are speckled or spotted, or of a colour entirely different from green. Hence we conclude that in those plants or parts of plants, the materials yielding chlorophyle are absent. We may sometimes observe, in summer, one single spot of a green leaf coloured red by the action of insects or by being injured by hail; the green colouring matter is at the spot decomposed by the light; no new portion is formed, and the spot acquires the same colour which the whole leaf would have assumed in autumn. From this we infer that the change of colour in the leaves during autumn is simply dependent on a chemical alteration of the green colouring matter by light.

Mulder, after showing from a large number of facts that wax along with a green colouring matter exists in leaves and unripe fruits,—wax with a red colouring matter, in the red leaves which appear in autumn, and in the red fruits,—and wax with a yellow colouring matter, in the yellow leaves of autumn, and wax with starch, in the yellow skins of fruits, gives a lengthened description of chlorophylle, for an account of which we must refer to the original work.

Berrillius's experiments, and those previously investigated by Bersellius, it appears that the green coloring matter of the leaves is readily decomposed into three different substances, one yellow, another blue, and a third black; and that according to the proportion of these three mixed with the green, a different kind of green must be produced. Hence the difference in the green colour of different leaves depends not only on the presence of more or less chlorophylle, but also on the different amount proportions of these colouring matters.

The quantity of pure C. chlorophylle contained in the leaves is exceedingly small; according to Bersellius, it is not more than the amount of pigment in dried cotton.

If a mixture of pure chlorophylle be exposed to the action of the sun, the green colour becomes in a few hours converted into a yellow. When a solution of pure chlorophylle in ether and hydrochloric acid was kept for five months in a bottle half full, the green was entirely changed into a yellow. From these experiments we learn, first, that the green colouring matter is decomposed and a yellow one left, both with and independently of the influence of light; and secondly that in all probability a substance produced by the action of light (companied with a compound resembling chlorophylle) is green colouring matter and green leaves is constantly going on under the influence of light. Mulder conceives that the continual decomposition of the green colouring matter may be in the wax, and that the external form of the leaf is found to have increased when the same leaves are analyzed later in summer. In consequence of the continuance of this reproduction the leaves remain green; when it stops, the leaves become yellow, as in autumn.

It is well known that the decomposed chlorophylle yields a blue colouring matter; it is this which is no doubt present in the skins of many fruits, as for instance those of the grape; the exact nature of the chemical change is not clearly known.

It is very obvious that the influence of light will convert starch into chlorophylle. Every part of an amylaceous root becomes green on exposure to light. The parts of plants which are green (except a few exceptions) contains starch; and in autumn as this green colour decreases, the starch also decreases, and finally cannot be detected by the iodine-test. Hence starch seems to form B. chlorophylle under the influence of light, and the latter substance is the same as that contained in the leaves, consisting chiefly of wax. The change of starch into botanical chlorophylle may be explained in much the same manner as its conversion into fat.

The wax contained in the leaves and other parts of plants may be chemically represented by the formula C_6 H_{12} O. Now if no other products be simultaneously produced we may suppose the wax obtained from the starch in the following manner:

\[
\text{6 equiv. of starch} \quad C_6 H_{12} O_6
\]

With 10 of water \quad H_2 O

Make \quad C_6 H_{12} O_6

And 4 of wax \quad C_6 H_{12} O

Leaving to be given off: \quad O_2

That is to say, 6 equivalents of starch yield 4 equivalents of wax, and give off 66 equivalents of oxygen. This fully explains the phenomenon why plants become green, evolve oxygen, and further indicates the use of starch in the leaves.

Mulder has, as far as we are aware, made only one ultimate analysis of pure C. chlorophylle—that from poplar leaves; for this analysis he calculated the formula C_6 H_{12} N O._

"Properly speaking," Mulder observes, "the green colouring matter in the leaves has nothing to do with the evolution of oxygen; on the contrary, the colourless C. chlorophylle, which seems to be everywhere present, becomes green by the absorption of oxygen. Hence a small portion of the oxygen produced from the conversion of starch into wax is employed for this purpose, and is not mixed with the atmosphere. This is just the reason why C. chlorophylle is not formed by the exhalation of oxygen; it only becomes green instead of white, as it previously was. This can only happen when there is an abundance of oxygen, and this we have seen to be the case when starch is converted into wax. We may therefore assume as proved that white chlorophylle diffused throughout the whole plant, will become green in proportion as starch is converted into wax; because it is enabled, in such proportion, to take up an oxygen, which is chemically represented, as already indicated."

"Now, the probable composition of green chlorophylle, C_6 H_{12} N O, shows that pure white chlorophylle is not produced from pure starch. It is necessary for the walls in a liquid state, should penetrate into the globule of starch, which during this transformation into wax is converted into C_6 H_{12} N O._ We do not know yet what that substance is, but it is certain that it must be one which is diffused throughout the plant like starch; hence it is probably protein, which is changed into a most beautiful violet-coloured substance by the influence of hydrochloric acid and oxygen."

We now return to the animal kingdom, and have a few remarks to offer on gelatin, a substance yielded by most parts of the animal body. Amongst the component parts of organized bodies, the most frequent is the gel. Modified in an infinite variety of ways, this substance is innumerable varieties exhibited both by plants and animals, in the external form, the structure, and consequently the functions of their organs. In the vegetable kingdom the substance employed in the construction of these cells is cellulose, combined with a little protein. In the animal kingdom the case is very similar, although the elementary form of the tissue and its chemical characters are different. In animals we must distinguish between the principal and the original cellulae, which, in the original in all probability varies in different cases, while the persistent exhibits a constant and general character. The persistent tissue is consequently a secondary product, and in this respect it is different from the primary one which is a primary or original one; neither has it an actual cellular form like the latter. There is however a resemblance be
between the two in several points, especially in relation to the large proportions in which they both exist, and to the several functions which they perform.

Gelatinous substance is also widely diffused over the body that it would exhibit the entire shape of the principal organs, even if all other constituents were separated. It constitutes the skin, the serous membranes, the cellular sheets of the muscles, the organ which is the most widely extended in the body; it is insoluble in cold water; acetic acid renders it soluble and prevents its petrolization; and when boiled it forms a jelly. It is in consequence of the last property that it has received the name gelatin. The gelatinous substance (skin, areolar tissue, serous membranes, &c.) is insoluble in cold water, and on boiling is physically and chemically altered. It will be seen on boiling nothing is taken up and nothing separated; the alteration being similar to that undergone by starch when heated in water.

The composition of gelatin is represented by the formula

\[ \text{Ca} \cdot \text{H}_2 \cdot \text{O}_3 \cdot \text{N}_2 \cdot \text{O}_6 + 6 \text{H}_2 \text{O}. \]

This peculiarity should be remembered, for the compound is likely to be formed in the preparation of broth, and in the application of Paget's Digestor to cooking; and it is regarded by Mädler as doubtful whether this hydrated gelatin can be again converted in the organism into nutrient matter, and whether it may not produce noxious substances in the body. As gelatin has been used in a very valuable kingdom, there is every reason to believe that it is produced in the animal body. It is most probably formed from the decomposition of the protein in the blood, through the action of the alkaline in the serum, and the existing influence of the atmosphere.

We are likewise imperfectly acquainted with the products of the decomposition of the gelatinous tissues in the body. Out of the body we know that by the influence of oxidation on gelatin prussic acid is formed, and that, by the action of alkalies, gelatin-sugar, leucin, and extractive matters are produced, while anasmin is disengaged, and an alkaline carbonate formed. Finely decomposed, it yields extractive matters with either gelatin-sugar or leucin. Since leucin is also produced from albumen when digested by pottasch, we perceive an intimate connexion between these products of digestion. Besides the gelatin obtained from cellular tissue and serous membranes there is another kind which has many of its properties in common with the gelatin, although it is described by Müller under the name of chondrin. It is obtained from the corns, and from those cartilages which do not ossify, by boiling them in water.

Its composition is 10 \( \text{Ca} \cdot \text{H}_2 \cdot \text{O}_3 \cdot \text{N}_2 \cdot \text{O}_6 + 8 \text{H}_2 \text{O}. \)

The preceding observations on the general organic substances which exist in the two great departments of the organic kingdom are sufficient for the clear understanding of the forms and properties of the elementary parts of plants and animals. Both kingdoms however contain an immense number of additional substances. In plants there are acids, bases, colouring matters, oils, and resins; in animals there are the various secretions, and in these vegetable productions have been fully treated of in many of the articles of the Penny Cyclopaedia, our attention will in the future part of this article be chiefly, confined to the animal products.

As there are few products by an animal other than milk, the most of which are secretions, and these vegetable productions have been fully treated of in many of the articles of the Penny Cyclopaedia, our attention will in the future part of this article be chiefly, confined to the animal products.

\* Light has recently found that albumen, fibrin, and casein contain more ash than is generally allowed, albumen containing about 8 per cent., and casein containing 4 per cent., of phosphate of lime.

\* The quantity of sulfur yielded by the formula for chondrin given in the text, and which is supposed to come from his own analyses.
TIS

the cell-wall; Mohl opposes this view, asserting that the nucleus lies within the cell at some distance from its mem-
brane. Valentijn has also made similar observations in many of the animal tissues. He has observed cases in which the
nucleus was not directly connected with the cell-wall, except by a few radiating fibres. Hence the function of the nucleus
in relation to cell-formation is still obscure.

Whenever cells are formed, numerous pre-existing nuclei are always present. They serve to form the contents of the
cell, while the cell-wall is probably formed from the delicate connecting medium which unites these minute granules. These
granules, which are the most minute organised particles with which we are acquainted, must be regarded as the most ele-
mental form of all organic structures, since they are a necessary condition for cell-formation; there can be no doubt that
they contain a protein-compound, since in the most recent structures in the animal and vegetable world protein is never
absent, and indeed appears to be essential to organisation.

The very simplest form of fungi (such as the common mould-
plant) are produced in non-nitrogenous bodies, such as lactic or tannic acid under the influence of the atmos-
phere (and therefore of nitrogen) and of water, contain protein from the first moment of their existence.

With regard to the distribution of the various forms of cells, we must notice certain dehiscence membranous ex-
ceptions in which no definite structure can be detected. They have been especially described by Bowman and Goodair, the formers being found in blood, lymph, and chyle, and the latter in the spleen and in the serous
membranes. This structure receives the former name from its
being the foundation or resting-place for the epithelium-cells which cover its free surface, whilst the latter appellation was
selected because it is a form of the primary cells of glands, and the source of secondary or secreting cells.1 Bowman
considers it to be simple or homogeneous. This is true as far as it contains no blood-vessels, and as regards its external and
attached layers; but as in its original condition it consists of cells, and when perfect contains nuclei at equal or variable
distances, it must not be considered as simply molecular.

Germinal membranes, observes Goodyer, 'are only met with on the free surface of parts or organs. One surface of the
membrane is therefore attached, and is applied upon a layer of arcellar texture, interspersed with a more or less
rich net-work of capillary vessels; while the other surface is free, and it is only on it that the developed or secondary

1. A portion of the germinal membrane of the human intra-glândular
lymphatics, with its germinal spots or nutritive centres diffused over it.

We now proceed to notice the history and functions of isolated animal cells. It is only during the last three or four
years that any correct ideas have been maintained regarding the importance of single isolated cells in the animal economy;

1. Formerly termed the primary membrane by the author.
rent the blood, as progressing in close contact with the walls of the vessels, is slower than that of the corpuscles, like the ordinary corpuscles, and seems to stick to each other. The exact functions of these corpuscles are still unknown, but there are many facts which seem to indicate that there is a decided relation between them and between the massive or organic life of the tissue.

Fig. 3.

1. Red corpuscles of human blood, exhibiting their flattened surfaces.
2. Red corpuscles of the blood of other animals, and those of man, so as to form rolls.
4. Colourless corpuscles of the blood of camel.
5. The same, enlarged by the imbibition of water.

On examining a drop of blood under a microscope, we find, in addition to those cells, which are comparatively rare, an immense number of what are termed red corpuscles, but which usually present a yellow appearance. These red corpuscles have been already noticed in the article Blood, P. C.

The following are the most important additions made to our knowledge of them since the publication of that article. The blood of many animals has been submitted to microscopic examination by Nasse, Wagner, Gulliver, and other observers.

In the article Blood it is stated that 'the red corpuscles of the blood have a circular form in all animals constituting the class mammalia.' A remarkable exception to this rule has been shown by Mandl to occur in the corpuscles of the camel tribe. The mean long diameter of the blood-corpuscles of the dromedary is to be found at the 32,548th of an inch, while the mean short diameter was only the 65,921st of the same standard. In the pac (Auchenia pacio) and guansaco (Auchenia glama) the blood-corpuscles scarcely differ in form and size from those of the dromedary, whilst in the vicuna they were slightly smaller.

The structure and magnitude of the human red corpuscles of the Camelidse such as the camelidse, are nearly as great as the smallest that have been observed in birds or reptiles.

The difference of size in the corpuscles of different mammalia is also worthy of notice. The average diameter of the human red corpuscles is 2,600th of an inch, but the average diameter of those of the elephant, according to the same observer, is as much as the 37,458th of an inch (which were the largest he observed amongst the mammalia), whilst those of the Napa musk-deer were no more than the 12,325th, and some were as small as the 16,000th of an inch in diameter. There is also a exception to the general statement that the corpuscles of the capillaries are oval; in one class, namely, the Cydtamons, or lamprey tribe, they are circular. Neither is the statement now correct that the corpuscles of the capillaries are the largest known; those of certain reptiles, as for instance the serpens and the poison, are considerably larger, and are even visible to the naked eye as minute specks.

There can be no doubt that the red corpuscles go through the same course as other cells. We have no doubt that the red corpuscles have been lost, and of the peculiar power which chalybeate medicaments have in forwarding their production. The precise method in which they are developed is however not exactly known.

With respect to the chemical composition of the blood-corpuscles, we have already stated that the globulin of which the walls are formed seems undoubtedly to be a protein-compound. The colour is due to a pigment which is received as the move of hæmoglobin. It has been generally assumed that this substance exists in two distinct states in arterial and venous blood, the pigment in the former being the excess of carbon and in the latter an excess of carbonic or carabolic acid. Mollier has however shown that its elementary composition is the same whether obtained from arterial or venous blood, and that it may be represented by the formula C, H, N, O, Fe; the following being the analyses from which he deduced it:

1, 2, and 3, were arterial, and 4 venous ox-blood; 5 was the mixed blood of a sheep.

It may be shown by conclusive experiments that the red colour is not dependent on the iron, for that constituent may be removed from the haematin without materially altering its tint, although it is very firmly combined with the four organic elements. The condition in which the iron exists in haematin—whether as an oxide, or as carbomula, or as a carburet, or in the metallic state—has long been disputed. According to Lichten the iron of the haematin is the most essential constituent of the blood in relation to the respiratory process. The following is his view of the theory of respiration:—Decomposition of the venous blood through the lungs, the globules change colour, and oxygen is absorbed from the atmosphere. Further, for every volume of oxygen absorbed, an equal volume of carbonic acid is, 'a most cases, given out. The red globules contain a compound of iron, and no other constituent of the body contains iron. Whatever change the other constituents of the blood undergo in the lungs, this much is certain, that the globules of venous blood are changed in colour, and that this change depends on the action of oxygen. Now we observe that the globules of arterial blood retain their colour in the larger vessels, and lose it only during their passage through the capillaries. All the constituents of venous blood which are capable of combining with oxygen, take up a corresponding quantity of it in the lungs. Experiments made with arterial serum have shown that when in contact with oxygen it does not diminish the volume of that gas. Venous blood in contact with oxygen is reddened, while oxygen is absorbed, and a corresponding quantity of carbonic acid is formed. It is evident that the colour of the blood in the venous globules depends on the presence of some one of these elements with oxygen; and that this absorption of oxygen is attended with the separation of a certain quantity of carbonic acid gas.

This carbonic acid is assimilated from the air, the serum does not possess the property, when in contact with oxygen, of giving off carbonic acid. On the contrary, when separated from the globules, it absorbs from half its volume to the whole volume of arterial carbonic acid, and the serum is not saturated with that gas. Arterial blood, when drawn from the body, is soon altered; its florid colour becomes dark red. The florid blood, which owes its colour to the globules, becomes dark by the action of carbonic acid, and this change of colour affects the globules, for florid blood absorbs a number of gases which do not dissolve in the fluid part of the blood when separated from the globules. It is evident therefore that the globules have the power of combining with gases. The globules of the blood change their colour in different gases; and this change may be owing either to a combination or to a decomposition. Sulphuretted hydrogen turns them blackish green and finally black; and the original red colour cannot in this case, be restored by contact with oxygen. Here a decomposition has obviously taken place. The globules darkened by carbonic acid become again florid in oxygen, with disappearance of carbonic acid, and the same thing takes place in nitric oxide. It is clear that they have borne undergone no decomposition, and consequently they possess the power of combining with gases, while the compound they form with carbonic acid is destroyed by it.

When left in contact with the air, the original red colour is still preserved, but it does not recover its florid colour a second time by the action of oxygen. The globules of the blood contain a compound of iron. A new solution of it takes place in red blood, we must conclude, that it is unquestionably necessary to animal life; and since physiology has proved that

Vol. II. — 4 N
the globules take no share in the process of nutrition, it cannot be that they play a part in the process of respiration.

The compound of iron in the globules has the character of an oxidized compound; for it is decomposed by sulphuretted hydrogen, exactly in the same way as the oxides or other substances of iron. By means of diluted muriatic acids, peroxide (seagull-oxide) of iron may be extracted, at the ordinary temperature, from the fresh or dried red colouring matter of the blood. The characters of the compounds of iron in the blood are not those of the peroxide, while the compounds of peroxide of iron, under other circumstances, give us oxygen with the utmost facility. Hydrated peroxide of iron, in contact with ordinary matters distilates of sulphur, is converted into carbonate of the protoxide. Carbonate of protoxide of iron, in contact with water and oxygen, is decomposed; all the carbonic acid is given off, and by absorption of oxygen it passes into the hydrated peroxide, which may again be converted into a compound of the protoxide. Not only the oxides of iron, but also the cyanides of that metal, exhibit similar properties. Prussian blue contains iron in combination with all the organic elements of the body; hence when decomposed, it gives off hydrogen and oxygen.

The air is rich in oxygen, and when placed in contact with these materials it is decomposed; but air is not the only source of oxygen. When it is exposed to light, cyanogen is given off, and it becomes white; in the dark it attracts oxygen, and recovers its black tint.

All these observations, taken together, lead to the opinion that the globules of the blood contain a compound of iron saturated with oxygen, which in the living blood loses its oxygen during its passage through the capillaries. This is shown when it is separated from the blood and begins to undergo decomposition. The compound, rich in iron, passes therefore, by the loss of oxygen, into one far less charged with that element. One of the products of oxidation formed in this process is carbonic acid. The compound of iron in the venous blood possesses the property of combining with carbonic acid; and it is obvious that the globules of the arterial blood, after losing a part of their oxygen, will combine with the carbonic acid to form haematin.

When they reach the lungs, they will again take up the oxygen they have lost; for every volume of oxygen absorbed, a corresponding volume of carbonic acid will be separated; they will return to their former state, that is, they will again acquire the power of giving off oxygen. For every volume of oxygen which the globules can give off, there will be formed (as carbonic acid contains its own volume of oxygen without condensation) neither more nor less than an equal volume of carbonic acid. For every volume of oxygen which the globules are capable of absorbing, no more carbonic acid can possibly be separated than that volume of oxygen can combine with the iron; but the absorption of oxygen causes the one volume of oxygen to combine with one volume of carbonic acid gas can be produced. And the absorption of one volume of oxygen can only cause directly the separation of an equal volume of carbonic acid; consequently the substance or compound which has lost its oxygen during the passage of arterial into venous blood, must have been capable of absorbing or combining with carbonic acid; and we find, in point of fact, that the living blood is never, in any state, saturated with carbonic acid; that it is capable of taking up an additional quantity without any apparent disturbance of the functions of the globules. Thus, for instance, after drinking effervescing wines, beer, or mineral waters, more carbonic acid must necessarily be expired than at other times. In all cases where the oxygen of the arterial globules has been partly or completely lost in the formation of carbonic acid, the amount of this latter gas expired will correspond exactly with that which has been formed; less however will be given out after the use of fat and of still-wines than after champagne. According to the views now developed, the globules of arterial blood give up the carbonic acid; and, through the capillaries, become saturated with the oxygen of the atmosphere, which constitutes the body. A small portion of this oxygen serves to produce the change of matter, and determines the separation of living parts, and their conversion into lifeless compounds of the oxides and hydroxides of the carbonic acid, and of the other elements of haematin, that is, it cannot be removed even by long digestion. Of the same kind is the fact that aquatic animals can exist in the lungs the oxygen has lost, and in consequence of this absorption of oxygen the carbonic acid in combination with it is separated.

Mulder is strongly opposed to this theory; he denies that such a compound as iron in venous blood, and he refers the process entirely to the oxidation of the protein-compounds. He alleges the following grounds against the probability of the correctness of Liebig's views:

1. It is not probable that there is a compound of iron in the blood connected with the other elements of haematin, that it cannot be removed even by long digestion. Of the same kind is the fact that aquatic animals can exist in the lungs the oxygen has lost, and in consequence of this absorption of oxygen the carbonic acid in combination with it is separated.

2. If, as Liebig asserts, peroxide of iron exists in arterial blood, and in the state of protoxide of iron in venous blood, almost any diluted acid would be capable of removing it. But this is not the case. Haematin, properly prepared, may be digested with dilute hydrochloric or sulphuric acid for many days without the absorption of any iron. From haematin treated in this manner Mulder obtained a precipitate of carbonic acid, and obtained 9.49 per cent. of peroxide of iron, which is the constant quantity always left after the combustion of well-prepared haematin.

3. The probability that the iron exists in a metallic state is strongly supported by the observation that hydrogen is evolved when a clot of blood is digested in sulphuric acid, and water is added. Mulder suggests that it occurs as an integral constituent of haematin in just the same manner that iodine occurs in sponge, sulphur in cystin, or arsenic in the caseyl series.

The importance of haematin in the whole mass of the blood is far too inconsiderable to carry a due supply of oxygen to the whole system.

Having thus shown the principal objections to which Liebig's celebrated theory is open, we shall endeavour briefly to explain the rival theory of Mulder. We have at an early part of this article shown that the protein-compounds are capable of undergoing oxidation when in contact with the oxygen of the air. When a protein-compound becomes oxidized, it assumes a metallic character, that is to say, it has a tendency to become solid and to adhere to solid substances. Now we have already mentioned that the blood-corpuscles are formed of globulin, and that globulin is the true primary globulin. When a respiration is performed, the exterior layer of such of the corpuscles as are exposed to the lungs to the action of the air, becomes converted into oxidized protein; it becomes flabby, and its red tint is bleached. These outer layers of the corpuscles exist in arterial blood. As they reach the capillary system, this white exterior layer is employed in the change of material of the body, and is in that way consumed. Having lost this white layer, they again become transparent. The red colouring substance in the corpuscles of arterial blood, shining through a white layer, must necessarily appear of a bright red tint, as may be shown by pouring dark red blood into a vessel filled with milky glass.

The preceding observations have been made with the view of showing the utility of those isolated animal cells—the blood-corpuscles—in the respiratory process. (We shall revert again to the distinctions between the characters of venous and arterial corpuscles in our remarks on the colour of the blood.)

In our remarks on various tissues we shall often again have to notice the functions of isolated cells. We shall now give another illustration of their utility, namely, their importance in the process of nutrition. Mr. Goodair has recently shown that there is a continual development of cells at the extremity of the capillary, and that the respiratory oxygen of these cells are the agents by which the secretion of the nutritive fluid is accomplished, and by which it undergoes its first preparation for the purposes it is subsequently to fulfill. The process now takes in to consideration the respiration and its recensions and ramifications.

As the chyle begins to pass along the small intestine, a
increased quantity of blood circulates in the capillaries of the gut. In consequence of this increased flow of blood, or from some other cause, the blood of the villi is thickened, and the internal surface of the gut throws off its epithelium, which is intermixed with the chyme in the cavity of the gut. The cast-off epithelium is of two kinds,—that which covers the villi, and which, from the duodenal fluids, may be nearly protective epithelium; and that which lines the follicles, and is endowed with secreting functions. The same action then, which in removing the protective epithelium from the villi prepares the latter for their peculiar function of absorption, throws out the secreting epithelium from the follicles, and thus conduces towards the performance of the function of these follicles. The villi, being now turbid with blood, erected, and nuclei, are covered or coated by the whitish-grey matter already described. This matter consists of chyme, of cast-off epithelium of the villi, and of the secreting epithelium of the follicles. The function of the villi now commences. The minute vesicles which are interspersed among the terminal loops of the lacteals of the villi, increase in size by drawing materials from the blood through the coats of the capillary vessels, which ramify at this spot in great abundance. While this increase in their capacity is in progress, the growing vesicles are continually exerting their absorbing function, and draw into their cavities that portion of the chyme in the gut necessary to supply materials for the chyle. When the vesicles have thus filled with their contents, they burst or dissolve, their contents being cast into the interior of the villi, as in the case of any other species of intestinal cell. The debris, and the contents of the dissolved chyle, have disabled the villus, and have already subserved the nutrition of the villus, pass into the looped network of lacteals, which, like other lymphatics, are continually employed in this peculiar function. As long as the cavity of the gut contains chyme, the vesicles of the terminal extremity of the villi continue to develop, to absorb chyle, and to burst, and their remains and contents to be removed along the lacteals. When the gut contains no more chyme, the flow of blood to the mucous membrane diminishes, the development of new vesicles ceases, the lacteals empty themselves, and the villi become fasicled. The function of the villi now ceases till they are again roused into action by another flow of chyme along the gut. During the intervals of absorption, it becomes necessary to protect the villi from the matters contained in the bowel. They had thrown off their protective epithelium when required to perform their functions, just as the stomach had done to afford gastric juice, and the intestinal follicles to supply their peculiar secretions. In the intervals of digestion the epithelium is rapidly reproduced."

Fig. 4.
that force which enables one primary secreting cell to distend itself with bile and another with milk.

Instead of growth being a species of imbibing force, and secretion on the contrary a repulsual, the one centrifugal, the other centripetal, they are both centripetal. Even in the latter state the two processes, growth and secretion, do not differ. The primary formative cell, after becoming distended with its peculiar nutritive matter, in some instances changes its form according to certain laws; and then, after a longer or shorter period, dissolves and disappears in the intercellular space in which it is situated; its materials passing into the circulating system if it be an internal cell, and being merely thrown off if it be an external cell. The primary secreting cell, again, after dissipation with its secretion, does not change its form so much as certain of the formative cells, but the subsequent stages are identical with those of the latter. It bursts or dissolves, and throws out its contents either into ducts or gland-cavities.

The general fact of every secretion being formed within cells, explains a difficulty which has hitherto puzzled physiologists, namely, why a secretion should only be poured out on the free surface of a gland-duct, or secreting membrane. We have attempted to illustrate Mr. Goodall's views by the accompanying figure.

**Fig. 5.**

1. Cells from the liver of **Botta ephesus**; the cellular division is dark blue and presents a chalky appearance.  
2. Cells from the liver of **Loxos cephalus.** In this instance the bile is contained in the cavities of the secondary cells, which constitute the nucleus of the primary cell.  
3. Cells from the mammary of a bitch. In addition to their nuclei these cells contain milk-sea.  

**Persistent tissus.** We now proceed to the histological and chemical investigation of the most important constituents of the human organism.

1. **Adipose tissus** is usually associated with areolar tissus (which acc), the two being generally known collectively as cellular tissus. It must be distinguished from fat, the former being a membrane of extreme tenuity in the form of closed cells or vesicles, while the latter is the material contained within them. The membrane of the adipose vesicle does not exceed the 20,000th of an inch in thickness, and is quite transparent; it is moistened by watery fluid, for which it has a greater attraction than for the fat it contains. Each vesicle is a perfect little organ, varying, when fully developed, from the 300th to the 800th of a line; minute capillaries may be observed on their external surface. When fat-vesicles are deposited together in large numbers, as is usually the case, they assume a more or less regular polyhedral form from their mutual pressure.

**Fig. 6.**

When the first traces of fat appear is not accurately known. In a well-formed five-months human foetus Valentin found in the subcutaneous cellular tissus of the sole of the foot not merely fat-cells, such as occur in adults, varying from the ordinary size to the 125th or 100th of a line, within and around which were numerous small vesicles (Fig. 6, a), but other forms which threw more light on their structure and development. In some the surrounding cell-membrane was much more distinct than as it occurs in adults (b). In other cases there appeared to be a deposition of fat, not occupying the whole space of the cell (c); the remainder of the cell having often a striped or streaky appearance, and forming a lateral projection; this is seen in c, and in a more marked degree in d and e. In other fat-cells there were observed to be two vesicles, separated by a septum, against which they were partially fastened by pressure (g), or merely separated by a constriction in the external walls, as in f. This form leads us to conclude that fat-cells increase by division. For the chemistry of this constituent we must refer to the article Fat, P. C., and to an early part of the present article. It is sufficient here to remark that the fat-vesICLE of the human subject contains margarin, a solid, and olein, a fluid fat. These sometimes separate spontaneously, presenting a very beautiful microscopic appearance. The margarin collects in a spot on the inner surface of the cell-membrane, and presents the appearance of a small star, whilst the olein occupies the remainder of the vesicle, unless when the quantity of fat in it is rather smaller than usual, in which case we may observe a little aqueous fluid between the olein and the cell-membrane. We have attempted to depict this separation in h.

2. **Pigment.** In certain parts of the animal organism we meet with definite and well-marked colorations, not dependent on any peculiar arrangement of fibres, &c., but on the presence of pigment-granules of various colours. These granules are usually inclosed in cells, termed pigment-cells. In all races of men we find a most remarkable development of these cells on the inner surface of the choroid coat of the eye, where they form several layers known as the *Pigmentum migrans.* They are probably always mingled with the epidermic cells, giving rise in the dark races to the deep colour of the skin; and presenting themselves in the white races in the form of freckles, the areola round the nipple, &c. The pigment-cells are usually flat and laterally compressed into the polygonal form. The granules in their interior are extremely minute, retain their dark colour under high magnifying powers, but exhibit various forms. In the choroid membrane of the human eye their form is very regular; in the adult no nucleus can be seen, a structure which is obvious in corresponding cells from the foetus. The pigment-cells have not always a simple rounded or polygonal form; they sometimes present remarkable stellate prolongations and other singular shapes, which we have attempted to depict in Fig. 9, representing pigment-cells from a frog. a, b, c, d, e, and g, Fig. 9, are representations of various pigment-cells from its choroid coat, while f is intended to exhibit the stellar shape in which these cells occur on the skin of that animal. The nucleus...
as sufficiently obvious in one of the cells in a, in c, d, e, and g.

4. It is known of the chemistry of the animal pigments. Scherer has made three analyses of the black pigment from the eye of the ox, from which he concludes that it consists of Carbon \ldots \ldots \ldots 58.264
Hydrogen \ldots \ldots \ldots 64.16
Nitrogen \ldots \ldots \ldots 13.768
Oxygen \ldots \ldots \ldots 29.090

From these analyses it appears probable that the black pigment contains a large amount of carbon than any other constituent of the animal body.

3. Horns, feathers, hair, scales, the various forms of epithelium and the crystalline lens. We shall confine our observations to the microscopic characters of epithelium and hair, and then briefly advert to the general chemical characters of the class.

The epidermis may be regarded as a delicate cuticle covering the free internal surfaces of the body, just as the epidermis (to which it is closely allied) invests the external surface. Some of the uses of the epithelial cells have been already noticed in our remarks on isolated cells, in addition to their obvious use in protecting the surfaces on which they are placed. This structure was first investigated by Henle (in Müller’s ‘Archiv,’ 1838), and has been studied carefully by Bowman (Art. ‘Membranes,’ in Todd’s ‘Cyclopedia of Anatomy and Physiology,’ 1842), Goodf. and others. From the forms presented by the epithelial particles they have received different names. Henle divided them into simple epithelium or tesselated epithelium, cylinder epithelium, and eli-epithelium, and although they frequently run in one another, yet on the whole these distinctive terms are serviceable.

**Fig. 10.**

The three forms of epithelium. The pavement epithelium consists of broad flattened particles, or scales, having an angular outline and a nucleus; these scales form layers of extremely variable thickness. Fig. 10, A, shows very clearly how they are superimposed over one another, forming an effective protection to the basement membrane beneath them. As a general rule the nucleus is large in proportion to the youth of the cell. In this figure we have attempted to exhibit these cells in two stages, a recent and a mature stage. In the young cells marked a the nucleus is relatively much larger than in b. This figure is intended to represent the epidermic scales of the frog; the larger cells, b, lying above the younger and smaller cells, a.

This form occurs on all synovial and serous membranes, and on most of the mucous membranes.

In the cylindrical epithelium the particles have the shape of small rods disposed endways on the basement membrane in a single layer. In consequence of their mutual compression they usually assume a prismatic rather than a cylindrical form, and hence Bowman applies the term prismatic to this form of epithelium. This form is perhaps best seen on the villi of the small intestine, or on the conjunctival surface of the cornes of the eye. We have attempted to depict the latter in Fig. 10, B.

The eli-epithelium is little more than cylinder epithelium on whose free surface numerous cilia or delicate filaments are observed in actual motion (Fig. 10, C). When in motion each filament appears to bend from its root to its point, returning again to its original state like corn moved by the wind. The motion of the cilia is not quite independent of the will of the animal, but seems even to be independent of the life of the rest of the body; it has been seen after the death of the animal, and proceeding with perfect regularity in parts separated from the body. Dr. Carpenter states that ciliary movement has been observed fifteen days after death in the body of a tortoise. The motion may be readily observed in the oyster or mussel. In the human subject this form of epithelium exists in the air-passage with their various offsets, as the nasal orifices, mustache ducts, \&c., and in the upper part of the vagina, the uterus, and the fallopian tubes. Its purpose is evidently to propel fluids over the surfaces on which it occurs.

Hair. The shape of the hair is that portion which is fully formed and projects beyond the surface. On examination we find it lodged in a follicle involution of the basement membrane (Fig. 11, a), which usually passes through the cells into the subcutaneous circular tissue. This hair-follicle is bulbous at its deepest part, like the hair which it contains. Its sides have a cuticular lining, b, continuous with the epidermis, and resembling the cuticle in the rounded form of its deep cells and the scaly character of the more superficial ones, which are here in contact with the outside of the hair, c. The hair grows from the bottom of the follicle, and the cells of the deepest stratum, there resting on the basement-membrane, are very similar to those which in other parts are transformed into scales of cuticle. A gradual enlargement occurs in these cells as they mount in the soft bulb of the hair, which indeed owes its size to this circumstance. If the hair is to be coloured, the pigment-grains are also here developed, for the most part in scattered cells, which may send out radiating processes; at other times, in a diffused manner around the nuclei of the cells generally. It frequently happens that the cells in the axis of the bulb become loaded with pigment at one period, and not at another; so that, as they pass upwards in the shaft, a dark central tract is produced of greater or less length, often only in irregular patches, and the hair appears here and there to be tubular, e. The shaft is much narrower than the bulb, and is produced by the rather abrupt condensation and elongation into hard fibres of the cells, both of those which contain pigment and those which do not.

The granules of pigment assumes a linear arrangement between the fibres, which are firmly united into a solid rod by a masticular similar, it may be supposed, to that which cements the scales of the cuticle.

The human hair has a proper bark, or cortex, formed in the following way:—A single layer of the cells immediately surrounding those about to form the fibrous tissue of the shaft are seen near the bottom of the follicle to assume an imbricated arrangement (Fig. 11, c), and gradually to mount on the hair, becoming more compressed against it in their ascent, until they form upon its surface a thin transparent colourless film, in which the overlapping of the delicate cells is still exhibited by elegant and exceedingly fine sinus.
The fibrous interior and this peculiar cortex together compose the shaft of the hair. By the close and emergent arrangement of the shaft from the follicle, fragments of the cuticular lining of the latter are apt to be drawn up upon the hair, sided probably in this by the imbrication of its surface, and are often found clinging around it in some way, but they are not to be regarded as any part of the hair itself. From the preceding description it will be evident that the fibrous part of the hair is a peculiar development of the cuticular cells resting on the bottom of the follicle, that the imbricated cortex is formed by a single series differently developed at the circumference of those, and that beyond this series comes the cuticular lining of the follicle, so that the hair is neither covered nor underlay by cuticle, but it is in fact the modified outside of the bottom of the follicle.

**Fig. 12.**

3. Transverse section of a hair of the head, showing the exterior cortex, the finnose with scattered pigment, and a central space filled with pigment. 4, a similar section of a hair at a point where no aggregation of pigment in the softest, 5, longitudinal section, without a central cavity, showing the imbrication of the cortex, and the arrangement of the pigment in the fibrous part. 4, surface showing the obvious transverse lines formed by the edge of the cortical annulus. 5, a portion of the margin, showing their imbrication.

The figures and the description of the structure are copied from Todd and Bowman's *Physiological Anatomy and Physiology of Man*, vol. ii, p. 418.

The chemistry of horny tissues has been specially investigated by Scherer and Van Laer. The following analyses of various tissues of this class have been analyzed by the former chemist (Liebig and Woehler's *Annalen*, vol. xi, p. 53):

From the analyses of Van Laer it appears that the average amount of sulphur in human hair is 5 per cent. From a series of well-derived experiments he concludes that "the hair consists essentially of -"

1. A connecting medium consisting of a tissue yielding gelatin, and represented by the formulas C6H10N2O2.

2. Of bismuth of protein, C6H10N2O2.

The large amount of sulphur is the cause of its colour being affected by various metallic salts. As there is no constant difference to be observed in the results obtained by the analysis of hair of various tints, it is to be presumed that the colour is dependent on peculiar arrangements of the ultimate particles. Hair further contains about 0.4 per cent. of peroxide of iron, which is supposed by Van Laer to be chemically combined with the protein.

**Fig. 13.**

Yellow fibrous tissue showing the entire and branched disposition of its fibres. Arolear tissue is dispersed over almost every portion of the body, being the substance most commonly (but incorrectly) termed cellular tissue. The following are the microscopic characters of this tissue, as described by Bowman and Todd:

When a fragment is examined, it presents an inextricable interlacement of tortuous and wavy threads, intersecting one another in every possible direction. They are of two kinds. The first are chiefly in the form of bands of very unequal thickness, and inelastic. Numerous streaks are visible in them not usually parallel with the border, though taking a general longitudinal direction. These streaks, like the bands themselves, have a wavy appearance, but can be rendered straight by being stretched. The streaks seen have more the marks of longitudinal creasing than a true separation into threads; for it is impossible to tear up the band into filaments of determinate size, although it manifests a decided tendency to tear lengthways. The larger of these bands are often as wide as the 5000th of an inch; the smaller can only be detected with high powers. These are the white fibrous element. The others are long, single, elastic, branched filaments, with a dark, decided border, and disposed to curl when put not on the stretch. They interfere with the others, but appear to have no continuity of substance with them. They are most commonly about the 8000th of an inch in diameter. These form the yellow fibrous element.

**Fig. 14.**

The two elements of Arolear Tissue in their natural relations to one another. a, the white fibrous element, with cell-nuclei, b, sparingly visible in it; c, the yellow fibrous element, showing the branching or anastomosing characters of its fibres; d, fibres of the yellow element, far finer than the rest, but having a similar circular diameter; e, nucleus cell-nuclei, often seen apparently lower.
These two tissues may be most easily discriminated by the addition of a drop of dilute acetic acid, which at once swells up the former and renders it transparent, while it produces no change in the latter. It thus brings into view corporcles of an oval shape, which are probably the nuclei of the cells from which the bands have been originally produced. Oval corporcles (Fig. 14, a), either altogether isolated or having very delicate prolongations with the adjacent threads, are sometimes noticed. They seem to be either advancing or receding stages of the tissue.

In Fig. 15, which represents the acral tissue from beneath the skin of a five-months fœtus, we can perceive the cells elongating into fibres.

In a chemical point of view the leading difference between the white and yellow tissues is, that the former is acted on by acetic acid in the manner already described, and yields a considerable amount of gelatin in boiling; while the latter resists the action of acetic acid, and yields little or no gelatin.

5. Nervous Tissue.—In a microscopic point of view nervous tissue may be separated into two elements, the neural, and the fibrous. The vascular nervous matter is grey or cinnibrous in colour and granular in its texture, containing nucleated nerve-rosettes, and being largely supplied with blood. The fibrous nervous matter is, on the other hand, usually white, and composed of tubular fibres, although in some parts it is grey, and consists of solid fibres; it is also less vascular than the preceding. The former is more immediately associated with the mind, and is the originating seat of the force manifested in nervous actions; while the latter is simply the propagator of impressions made on it. The union of these two kinds of matter constitutes a nervous centre, and the threads of fibrous matter which pass to or from it are called nerves. The smaller nervous centres are termed ganglia; the larger ones are the brain and spinal cord.

Two species of primitive fibres have been observed by microscopists in the fibrous matter; they have been named the tubular fibre, or the nerve-tube, and the gelatinous fibre; the latter is comparatively rare, and is seldom found except in the sympathetic system. The tubular fibre is a tube composed externally of a fine transparent homogeneous membrane, very much resembling the sarcodermum of muscle, which will be presently noticed. Nucleated cells may however be occasionally seen in it, as in Fig. 16, which represents a portion of the acutaneous nerve of a frog. This may be termed the tubular membrane of nerve. The contents of this tube consist of a soft, semi-fluid, whitish, pulpy substance, which is readily pressed out of its cut extremity. This is termed by Ehrenberg the white substance, since the white colour of the nerve-tubes is dependent on it. Within this and occupying the centre of the tube is a transparent, somewhat flattened band, which is extremely delicate, and in which it seems possible to recognize any more definite structure. Hence the tubular fibre consists of these distinct elements.

The tubes when quite fresh are perfectly cylindrical; but very slight pressure or almost any disturbing influence gives rise to swellings or enlargements in the course of the fibres, causing it to assume a varicose appearance. Two conditions seem to favor the production of this change; namely, a feeble power of resistance in the tubular membrane, and a semi-fluid state of the contained nervous pulp. In the nerves of the extremities the tubes are very delicate in structure, and are very apt to exhibit this change of form, and in the brain and spinal cord they present the same tendency. We mention this appearance because Ehrenberg formerly supposed that these varicosities were natural and existed during life, and that they furnished a valuable morphological character of the nerves of the spinal senses and the cerebro-spiral centres.

In point of size the nerve-tubes present considerable variety even in the same trunk; and in the different classes of animals the differences are well marked.

In man and other mammals they vary from the 128th to the 6500th of an inch, in birds, from the 3000th to the 3000th of an inch; in reptiles—in the frog—from the 1290th to the 2800th of an inch; in fish—in the eel—they are the 104rd of an inch, and in the optic nerve of the cool-fish they are the 850th of an inch. These primitive tubes present no subdivision or branching. Whatever be the connexion which such primitive tube forms with the nervous centre and with the textures to which it is distributed, it passes from one point to the other without any change, save perhaps in size, and without any communication with neighbouring tubules, beyond possibly investment by a common sheath.

The gelatinous nerve-fibre is a term applied by Ehrenberg occurring principally in the sympathetic nerve, and which may be regarded as its distinctive element. They are flattened, soft, and homogeneous in their appearance, bearing a considerable resemblance to unstripped muscular fibres; and like them, they contain numerous cell-nuclei, which are frequently arranged in a tolerably regular manner. These nuclei are brought in view by acetic acid, which dissolves the rest of the fibre, leaving them unchanged. These fibres contain nothing analogous to the white substance of Schwann, and hence are devoid of that whiteness which characterizes tubular fibre. It seems that the grey colour of certain nerves depends chiefly on the presence of a large proportion of the gelatinous fibres. Hence they are sometimes termed grey fibres. They are usually smaller than the tubular fibres, their diameter ranging between the 6000th and the 6000th of an inch. Both classes of fibres appear to run continuously from one extremity of the nervous cord to the other, without anything like union or anastomosis; each ultimate fibre probably having its distinct office which it cannot share with the other.

We now proceed to the consideration of the vascular nervous matter, which in its normal form may be regarded as gkelig (Fig. 18, A, a, and B, a). This form is however liable to great variation, and from the comparison to which these nerve or ganglion-globules, as they are termed, are exposed, they may become oval or polygonal, or they may extend
The wall of each vesicle consists of an exceedingly delicate membrane, containing a soft but tenacious finely granular mass. The nucleus is generally eccentric, much smaller than the containing vesicle and adherent to some part of its interior. Its structure is apparently the same as that of the outer vesicle. The nucleus is a minute, remarkably clear, and brilliant body, also vesicular, enclosed within the nucleus. The processes to which we have alluded contain the same granular matter as the cells, with which they seem to be continuous. They are extremely delicate, and generally break off close to the nucleus; sometimes however they may be traced to a considerable distance, and will be found to divide into two or three branches, which undergo further subdivision. It is most probable that they either serve to connect distant vesicles or that they become continuous with the flattened bands occurring in the centre of the tubular element. In most situations where vesicular matter is found in the nervous centres, tubular fibres and sometimes both varieties of fibre are also present. We have attempted to depict this union in Fig. 18.

**Fig. 18.**

A, vascular and fibrous matter of the lamina of the cerebellum; b, ganglion-globule; c, very minute nerve-tube traversing a finely granular matrix, in which are numerous rounded nuclei.

Fig. 19.

A, nerve from the finger, natural size, showing the Pacinian corpuscles; b, unusual form from the mesentery of the cat, showing two included in a common envelope; c, are the two nerve-tubes belonging to them; d, another from the same, showing an effect from the central cavity, containing a branch of the nerve; e, rare form from the mesentery of the cat, showing two corpuscles placed in succession on a single stalk, and furnished with the same nerve-tube, which traverses the white substances in the interval between them. From Todd and Bowman.

**Fig. 20.**

Pacinian corpuscles from the mesentery of a cat, intended to show the general construction of these bodies. The stalk and body, the outer and inner system of capsules, with the central cavity, are seen. a, Arterial twigs, ending in capillaries, which form loops in some of the interstitial spaces; and one penetrates to the central capsule. b, The inner or innermost of the stalks, prolonged from the neurolemma. c, Nerve tube advancing to the central capsule, there losing its white substance, and stretching along the axis to the opposite end, where it is fixed by a tubular enlargement. Todd and Bowman.

In the above figure, which exhibits the general structure, the ten or fifteen innermost capsules may be observed to be in contact with one another, while the rest are separated by a clear space containing fluid.

Respecting the function or use of these corpuscles no satisfactory account has yet been given. Pacini is himself inclined to believe that they may be concerned in the phenomena of what is called animal magnetism.

6. **Muscular tissue.** There are two forms of muscular fibre, differing extremely in their microscopic characters. The fibres of the voluntary muscles, as well as the fibres of the heart and some of those in the oesophagus, are striped or striated; while all other muscles, including those of the alimentary canal, the uterus, and bladder, all of which are involuntary, are unstriped or non-striated. [Mivart. P. C.]
The elementary fibres of the voluntary muscles are arranged in sets parallel to one another, whilst those of the involuntary muscles usually cross at various angles, and interfere, forming membranous organs, enclosing a cavity which their contraction serves to constrict.

The striated fibres are usually of about the same length as the muscle to which they belong. In the sartorius they often exceed two feet in length, whilst in the stapedius (in the middle ear) they are not two lines. They vary in diameter from the 60th to the 1600th of an inch, being largest in crustacean fish, and reptiles, where their irritability is most enduring, and smallest in birds, where it is most evanescent. In man their average diameter is the 400th of an inch. The fibre always presents upon and within it longitudinal dark lines, along which it subsequently splits up into fibrillae; but it is by a fracture along that these fibrillae are often detached, though they do not exist as such in the fibre. Sometimes, on the application of violence, cleavage takes place in a different manner, in a plane at right angles to the long axis of the fibre. In this case discs, and not fibrillae, are obtained; and the cleavage is just as natural as the former, though less frequent.

Fig. 21.

A

B

Fig. 22.

2. That fibrillae taken from any part of a fibre are marked with light and dark points, corresponding in distance and force with the transverse stripes of the fibre.

P. C. S., No. 167.

3. That with a high magnifying power applied to a single fibre we may bring all parts of its interior into focus in succession, and perceive throughout the same kinds of stripes.

The Sarcodeomys or tubular sheath enveloping the striated fibre, consists of a transparent, very delicate, but tough and elastic membrane, which isolates the fibre from all other tissues. It most commonly has no appearance of structure, but occasionally small corpuses, the remains of cells, are observed in it.

Fig. 23.

If the fibre be immersed in acid, it swells, bursts the sheath, and forms small protrusions or herniae.

The researches of Valentin and Schwann have thrown much light on the development of muscles in the embryo. In its earliest stage, muscle consists of a mass of unstriated cells which first arrange themselves in a linear series, and then unite to form the elementary fibres.

Fig. 24.

Stages of development of striated muscle fibre.

a. Arrangement of the primitive cells in a linear series.

b. The cells united, the nuclei separated, and some broken up; longitudinal lines becoming apparent. From a bird's eye, three inches long.

c, d, e. Transverse stripes apparent. In c the nuclei are internal and lodge the disc; in d, if they are placed on the surface. From a fetal cell, two months old.

d. Transverse stripes fully formed and dark; nuclei disappearing from view. From the human fetus at birth.

f. Elementary fibre from the adult, treated with acid, showing the nuclei a from Schwann. The rest from Bowman.

As the cells unite, a deposit of contractile material gradually takes place within them. The deposition assumes a granular form, the granular or sarcomatous elements being of the same size as the perfect muscle; for this reason the transverse stripes resulting from their apposition are of the same width as in the adult. Muscles grow by an increase, not of the number, but of the bulk of their elementary fibres.

The unstript or non-stripled fibres consist of flattened bands, generally of a pale colour, bulged at intervals by oval or elongated corpuses. Their texture seems to be homogeneous. By transmitted light they have usually a soft and very finely motled aspect; their ordinary diameter varies from the 3000th to the 2000th of an inch.

Chemical characters of Muscle.—In consequence of the difficulty that exists in separating muscular fibre from arterial tissue, vessels, and nerves, it is impossible to speak with certainty regarding its behaviour towards reagents. Playfair and Bouchekann have analyzed the dried muscular flesh of the ox, and found it to be identically in its composition with dried blood. For an account of the flesh of man and of various animals we refer to Simon's Chemistry, vol. ii. p. 422-425.

7. Cartilaginous Tissue.—The simplest form of cartilage consists merely of nucleated cells, and closely resembles the cellular tissue of plants. This kind is found in the rudimentary spinal column of the early embryo; it also exists in the chorda dorsalis of the cartilaginous fishes. In other kinds of cartilage the cells are embedded in an intercellular substance, presenting certain varieties of appearance.
In articular cartilage the cells are oval or roundish, dispersed in groups through a nearly homogeneous intercellular substance. The cells measure from the 1,800th to the 900th of an inch. In the interior part of the intercostal cartilages the cells usually assume a more or less linear arrangement. In the different cartilages the cells vary in size and form. For the chemistry of cartilage, see Simon, vol. ii. p. 415.

8. Osseous Tissue has, during the last few years, been examined closely, with much success. These examinations have increased our knowledge of the nature of bone, as regards both its minute structure and its development. We must here confine ourselves to the former point.

The canals which are everywhere found traversing variously the substance of bone, and giving passage to the blood-vessels for the nourishment of the tissue, are called Haversian Canals, a name given them in consequence of Clopton Havers having been the first who gave a full account of them. The parieties of these canals have a laminated arrangement. The laminae themselves are numerous and placed concentrically; the internal laminæ, that which is in immediate contact with the vessel or vessels, being the most distinctly marked, and each succeeding one having a less distinct outline.

Besides the concentric lamina, there are others which surround the exterior of the bone, and may be known as the superficial lamina. In connexion with both the concentric and superficial lamina are a third set, which cannot belong to either of the other orders, but which are placed between them, and form the bond of union between each system.

Much has been lately written on the bone-corpuscles. These are small cells, of oval form, placed between the laminae, and having numerous distinct tubules running from them in almost every direction. They have been sometimes compared to a spider with many legs. The corpuscles, or, as they are occasionally called, the calcified cells, have a definite relation to the Haversian canals and to each other.

The Haversian Canals, the osseous lamina, and the bone-corpuscles are therefore the leading points to be mentioned in treating of the structure of the bone. Upon a closer view, however, it will be seen that it is only the lamina which are

**Fig. 27.**

Bone; the canals and corpuscles are spaces existing in bone, and are not really necessary to the existence of osseous tissue, though they are requisite where the amount of substance is appreciable to the unaided senses.
They vary very much in number, but the most common amount is ten or twelve. Of these, the internal laminae, which forms the parieties of the Haversian canal, is most distinctly marked, while each succeeding one as we proceed outwards becomes less distinct. Connecting these Haversian systems is a second series of laminae, without which the former would exist but as a bundle of loose tubes (Fig. 9. 4). In this substance we find the laminated arrangement least distinct, far less regular, and the laminae individually subject to great irregularity of thickness. They are generally more transparent than either the Haversian or external systems. The last division consists of those laminae which surround the exterior of the bone. These have greater individual extent, but are the least numerous. They are continuous with the laminae of the Haversian system whenever the latter arise at the surface of the bone; the external laminae, if this case being continuous with the inner lamina of the Haversian system.

The effect of madder upon the osseous system, when given to an animal with its food, may here be noticed, since the colour is imparted to the bone. By introducing madder into the stomach, a deep red tinge is very soon observed: in a pigeon the bones were rendered brilliantly red in twenty-four hours. A similar effect was produced on a young pig in three weeks. On making sections of bone so affected, the colour is found to be present in the external lamina of the bone, and in the inner lamina of the Haversian system, thereby proving that the action of colouring takes place upon those surfaces which lie in contact with vessels.

Of the Haversian canals.—These canals must be considered in relation to their number, size, and the parts which they contain. The number of canals in a given space vary perhaps a little, but this variation will be regulated in some degree by the situation of the bone, but more especially by its age. Thus the transverse section of the femur of a human fetus of seven months will present many more canals than a section of equal measurement from the femur of an adult. The size of the Haversian canals takes a considerable range, varying from the 300th to the 500th of an inch. The Haversian canals undeniably passage to blood-vessels, this being their principal if not only purpose.

The corpuscles or cells of bone cannot be described as having any definite unvarying shape or size. The general form is a compressed oval, though not unfrequently they are circular. Again, they are sometimes almost triangular in their outline, while in other instances they approach a linear shape. These are the most common varieties of outline to which the bone-cells are subject, as they occur in the bones of man and the higher animals. In the four great classes of animals, namely mammals, birds, reptiles, and fishes, it has been shown by Mr. Quellett that there are certain characters connected with these cells by which a bone of one class may be distinguished from that of another. He has shown that they are smallest in birds, a little larger in mammals, and largest of all in the reptiles; while in fishes they are altogether unlike those in the preceding classes. The importance of this observation in relation to fossil osteology is obvious. Connected with the canals are numerous branching tubes, which are slightly dilated as they enter the cells. The number arising from each cell does not allow of any very definite enumeration, since these cells shall be found possessed of a like number of branching tubes. The general arrangement of the tubes is radiate, as regards the cells which form their common centre. The connexions are so numerous between the tubes and between the cells through the tubes, that a fluid introduced into one cell in a bone, may enter every other cell in that bone. The cells are situated between the laminae, or on their surface; but where concentric laminae exist, the cells in the Haversian system, the cells are placed in circular lines between the laminae, each line of cells having the Haversian canal as an exit common to it and the connecting lamina. When the canals for vessels are in great abundance, the bone-cells are more rarely met with; indeed in some cases they are almost entirely absent. When the cells are seen by transmitted light, particularly in a transverse section of bone, they are frequently opaque. There is no doubt that the bone-cells perform the function of circulation.

The Chemistry of Osseous Tissue has recently met with much attention from Valentin, Lehmann, Marchand, and more especially Von Bibra. From the latter we have gathered forty years, who committed suicide, Lehmann obtained—

For a full account of the chemistry of bone we must refer to Simon’s ‘Chemistry,’ vol. ii. pp. 356-414, or Von Bibra, ‘Chemische Untersuchungen der Knöchen,’ &c, Schweinfurt, 1844.

9. Tooth.—The structures entering into the composition of the tooth are three: dentine, or tooth-substance; enamel; and cement, or more properly bone-tissue. The enamel invests the more prominent parts of the crown, from which points it gradually diminishes in thickness, till it terminates in a line on the neck of the tooth. The cement, or dental bone, is thickest at and near the end of the root, and gradually becomes thinner as it advances towards the crown of the tooth. In a tooth that has been used for some little time, the cement terminates where the enamel commences, but there is reason to believe that a thin layer is continued over the enamel. Of these tissues, do not forming the great bulk of the tooth, and thereby becoming the most important, will first demand our attention. The pulp-cavity occupies the centre of the dentine, and on its surface are superincised the enamel and the tooth-bone, the former investing the crown, the latter the layer of the surface of the fang. These two tissues form a layer of variable thickness in different parts of the teeth. This layer, however, is soon worn off when the tooth comes into use. If the enamel and cement are removed from a tooth, and the dentine alone allowed to remain, the tooth still retains much of its original shape, losing most at the two extremities, while in point of size the loss sustained is comparatively slight; thus showing the dentine to constitute by far the greater portion of the tooth.

The dentine is made up of two distinct parts: first, dental tubes; secondly, intertubular tissue. The tubes have distinct parities, equal in thickness to their calibre. In some instances they appear to contain a minute granular matter, but in many, perhaps in the majority of cases, they are perfectly free from solid contents. If a vertical section, passing through the pulp-cavity, be taken for examination, the dental tubes may be traced from their commencement on the surface of the pulp-cavity, to their termination at the junction of the cement, and the dentine on the enamel of the latter, or they may be seen passing into these external structures. The tubuli commence at a right angle with the surface of the pulp-cavity, and proceed outwards towards the surface of the tooth, giving out in their way numerous small branches, which, meeting with other similar branches, either unite with them, or meeting with simple cells in the intertubular tissue, there terminate. Towards the surface of the dentine it is uncommon to see a tube alter its course, and by joining another, form a loop. The tubes all commence in the pulp.
in character of formation, could give a coarse illustration. The granularity is best seen near the external surfaces of perfect dentine, or in the tissue when developing. In the intertubular regions, the hemispheroid or oval cells are found, especially near the surface of the dentine of the flank, as a great mass of thickenings, resting on a large number of thin, flat and closely united cells. Their thin plate is an approximation to a six-sided prism, and their sides are relatively uniform, being about the six times in diameter or diameter, at the least, to the distance taken by the observer for the most part vertical to the surface of the dentine uniform, which they rest; those therefore which proceed from the base of the crown and rise vertically, while those from the external surface of the teeth will be horizontal. When the coronal surface of the dentine is concave, the enamel fibres of the opposite sides of the concavity form with each other, and meet at their external ends. This juncture is imparted imperfect, and leaves a fissure, under which the dentine, being less protected from external influence than on other parts of the crown of the tooth, is more frequently attacked by disease. The fissures on the crown of the molars are often subject to this defect of development. The ends of the enamel fibres are received into shallow hexagonal depressions in the coronal surface of the dentine, whence in course of time they frequently describe curves. The distribution of the fibres in the intertubular fibres is sometimes perfectly parallel; indeed, they often diverge or cross each other at considerable angles. The curves also seem less regular than those formed by the dentinal tubes.

The degree of the neck, or that by which the surface of the teeth communicate with the bone. When the dentine is received into a layer of bone, it is slightly altered, as the area of the bone is divided into two or three branches of varying proportions, and by entering the external foramina, the branches of the bone receive a much deeper impression on the surface of the bone. The depth of the dentine, then, which enters the bone, is not much different from the bone-cells, and in a similar manner, and with a much deeper impression. The depth of the dentine, then, which enters the bone, is not much different from the bone-cells, and in a similar manner, and with a much deeper impression. The depth of the dentine, then, which enters the bone, is not much different from the bone-cells, and in a similar manner, and with a much deeper impression. The depth of the dentine, then, which enters the bone, is not much different from the bone-cells, and in a similar manner, and with a much deeper impression.

For the importance of the microscopic investigation of the teeth in the classification of existing and the determination of extinct species of vertebrates, we must refer to Prof. Owen's 'Class of Vertebrata.' One of the most splendid works ever published.

Chemistry of the dentine. - Von Bibra has instituted numerous analyses of the teeth of man and the lower animals. We select the following by way of illustration:

- Molar tooth of a woman of an aged 25 years.
- Molar tooth of an adult male.
- Enamel, portion of dentin.
- Dentine, portion of dentin.
- Phosphate of lime, with a little flocculent alkali. 8â‚¬â€†6â€†5â€†7â€†4â€†9â€†6â€†2â€†6â€†0â€†7.
- Carbonate of lime. 8â€†8â€†7â€†7.
- Phosphate of magnesia. 2â€†5â€†2â€†9.
- Soluble salts. 0â€†9â€†1.
- Cartridge. 2â€†9.
- Fat. 0â€†5.
- The osseous portion includes the dentine and cement.

We have thus taken a brief survey of the microscopic and chemical characters of the most important structures entering into the composition of the human body. In addition to this, and perfectly distinct from these are numerous more or less results of disease. In this class we must place granular cells, the various forms of morbid tumours, cancer, ulcerative, scrofulous, etc., and part of the cataracts and ulcerative of the disease. Within the scope of this article; and for information regarding them we must refer to Vogel's 'Pathological Anatomy of the Human Body,' an English translation of which has recently appeared by Dr. De la Rue.

Section III. - Nutrition and the Secretions.

We shall here notice those points in the chemistry of the blood - the general nutrient fluid - which have been the subject of investigation by our best investigators. The whole subject of nutrition, in connexion with the blood, has been treated by Dr. Poole, P. C., and adopted a similar course in relation to the various sections already就够了 by it.

We shall, in the first place, however, offer a few remarks on nutrition, with the view of bringing up the article Food, P. C., up to the present state of our knowledge. The classification of foods in that article is not at present adopted by chemists and physiologists.
There are very strong reasons for believing that foods containing nitrogen are alone capable of conversion into blood, and of forming organised tissues; hence Liebig has termed them the plastic elements of nutrition. The non-nitrogenous foods are, according to Liebig, incapable of conversion into blood, and are therefore incapable of forming organised tissues. They are, however, not without their use; their function, according to Liebig, to support the process of respiration. The blood-corpuscles are formed in the bone-marrow; the expenditure of oxygen is attended with the development of heat. These latter foods bear the terms the elements of respiration.

Nitrogenous Foods, or Protase, is a Substance of Eminent Right.

Vegetable fibrin. Fat, Pectino.

Vegetable albumen. Starch, Borsone.

Vegetable casin. Gum.

Animal flesh. Cane-Sugar, Beer.

Animal blood. Grape-Sugar, Spirits.

Sugar of Milk.

Liebig believes that a second use (an abnormal rather than a natural one) of the second group is, in relation to the formation of fat (p. 636). Moreover, the statement contained in the article Foons that 'gelatin is a highly nutritious principle requires some notice. Liebig has established it as a law that "no nitrogenous compound, the composition of which differs from that of fibrin, albumen, or casin, is capable of supporting the vital processes in animals." The animal organism," he observes, "unquestionably possesses the power of forming from the constituents of its blood, the substance of its membranes, as of cellular tissue, of the nerves and brain, of the organic part of cartilage and bones. But the blood must be formed to it newly formed in its body but its form— that is, in its chemical composition. If the body is alone, a period is rapidly put to the formation of blood, and consequently to life. For this reason gelatin, which, as we have already shown (p. 620), is not a protein-compound, cannot form blood, and therefore will not support the vital processes. The two following facts seem however to show that it has a use in the economy. When in the body of a starving or sick person the fat disappears, and the muscular tissue takes the form of blood, we find that the tendons and membranes retain their natural condition, and the limbs of the dead body retain their connexions, which depend on the gelatious tissues. On the other hand, the gelatin of bones devoured by a dog entirely disappears, whilst only the bone-earth is found in the excrements. The same is true of man when fed on food rich in gelatin; as, for example, strong soup. The gelatin is not to be found either in the urine or in the faces, and consequently must have undergone a change, and have served some purpose in the animal economy: in other words, it must have been expelled from the body in a form as similar as possible to that in which it was formed. From these facts Liebig infers to the belief that gelatin is serviceable in the formation of cellular tissue, membrane, and cartilage; and that it may tend to the reproduction of such parts of the body tissues as have been converted to bones. And when the powers of nutrition in the whole body are affected by a change of the kind, then, even should the power of forming blood remain the same, the organic force by which the constituents of the blood are transformed into cellular tissue and membranes must necessarily be enfeebled by sickness. In the sick man the intensity of the vital force—its power to produce metamorphoses—must be diminished as well in the stomach as in all other parts of the body. In this condition, the uniform experience of practical physicians shows that gelatinous matters, in a dissolved state, exercise a most deciding influence on the state of the health. Given in a form adapted for assimilation, they serve to husband the vital force, just as may be done in the case of the stomach, by means of the food in general. Brittleness in the bones of the graminivorous animals is clearly owing to a weakness in those parts of the organism whose function it is to convert the constituents of the blood into cellular tissue and membrane; and if we can trust to the reports of physicians who have resided in the East, the Turkish women, in their diet of rice, and in which gelatin acts not, no one who has seen much medical practice will exist as a soda compound. Some of the cases, of the stomach, in which we have missed the conditions necessary for the formation both of cellular tissue and of fat. Whether this be the mode in which gelatin acts or not, no one who has seen much medical practice will exist as a soda compound. We now proceed to make those additions to the chemical portion of the article Blood which the labours of the last ten years have rendered necessary.

We have already (in our remarks on isolated cells) noticed the additions that have been recently made to our knowledge regarding the blood-corpuscles of various animals. Numerous observations have also been made on the changes in form which the corpuscles undergo in various diseases (Simon's 'Animal Chemistry,' translated, with additions, by Day, vol. i. p. 102, London, 1845; published by the Sydenham Society); also on the effects of various medicines and re-agents on the corpuscles (Ann. Ch., vol. 115, pp. 107-112). Additional information on the acceleration or retardation of the coagulation may be found in Hamburger's Thesis on that subject, published at Berlin in 1839, and in Simon, 'An. Ch.' With regard to the chemical composition of the blood, we may regard it as usually containing the following ingredients:—

1. Water.
5. Carbonate of lime, magnesia, and soda. Calcium carbonate.
8. Urea—a trace.
9. Sugar—a trace (?).

It will be observed that there are notes of interrogation to several of the salts: the presence of these constituents is denied by Enderlin and Liebig's school generally. Their objection is founded on the circumstance, that if these salts were exposed to a red heat, they would become converted into carbonates; and that the ash obtained from the incineration of the animal body, we shall give the leading grounds on which the presence of carbonate of sodium is disproved, and its alkalinity is otherwise accounted for:—

The ash does not effervesce on the addition of an acid.
2. Hot water poured over the ash becomes alkaline; it holds in solution alkaline phosphates and sulphates, chloride of sodium, and sometimes chloride of potassium, but no other salts.
3. On the addition of a neutral solution of nitrate of silver to this fluid, there is a yellow precipitate which is partly soluble in nitric acid; a portion however consisting of chloride of silver remains unsolved. The addition of nitric acid causes no effervescence. On neutralizing the acid filtrate with ammonia, a yellow precipitate of trisubphosphate of silver (3 A O, P 2 S 2 O 7) is thrown down.
4. On treating the aqueous solution of the ash with a solution of chloride of calcium, there is a copious gelatinous precipitate of phosphate of lime (3 A O, P 2 S 2 O 7) which dissolves in nitric acid without effervescence. On treating this acid solution with nitrate of silver, and neutralizing with ammonia, the trisubphosphate of silver is precipitated as before. The addition of the chloride of calcium neutralizes the previously alkaline fluid. From 1, we see that the alkaline reaction is not due to the presence of alkaline carbonates; and 2 shows it is not dependent on the presence of free potash or soda, for otherwise the fluid would not be neutralized by the chloride of calcium. Hence the ash in the blood cannot exist as a soda compound. The solution therefore is of carbonate of sodium, but there be alkaline lactates, acetates, nor fatty-acid salts in that fluid; and on the above grounds Enderlin conceives that we are justified in assuming that the alkaline reaction of the

Therefore regarding the salts actually occurring in the blood is however far from settled, Ludwig having during the last few months positively denied Eberlin's statements: (See Day's "Report on the Progress of Chemistry," in Rankine's Half-yearly Abstract of the Medical Sciences, vol. iii., 1846.)

Generally speaking it is only requisite in the analysis of the blood, to determine a few of the most important constituents; as, for instance, the water, fibrin, blood-corpuscles (globulin and hematin), and the solid residue of the serum (the organic portion and the salts). For this purpose we may adopt the following simple plan lately published by Figuer. It is based on the fact, well known many years ago by Berzelius, that after the addition of a solution of a neutral salt to destributed blood, the globules do not (as before) pass through the filter paper. On the addition of two parts of solution of sulphate of soda of specific gravity 1130 of one blood, Figuer found that the whole of the corpuscles remained on the surface of the filter. The following are the steps in this process. The fibrin is removed by stirring, drain and weighed; the weight of the corpuscles is ascertained by the method indicated, and that of the albumen by coagulating by means of heat the filtered solution. The proportion of water is known by evaporating a small known weight of the blood. The filter containing the corpuscles should be dipped in boiling water, which removes any sulphate of soda that may be present, and at the same time renders the corpuscles insoluble. Separate and frequently difficult processes are required to detect those ingredients which occur in small quantity or only in morbid conditions.

Distinctions between Arterial and Venous Blood.—We have already (p. 102) mentioned the circumstance that the external envelope of the blood-corpuscles becomes converted during the act of respiration into oxidized protein, and that the bright red colour of arterial blood is owing in part to the modifying influences of the white investing membrane. But there is yet another mode in which it acts. The buoyant mass which is frequently observed on the upper part of the clot in inflammatory diseases is very apt to curl up and become concave. Now this buoyant mass consists of the outer part of the oxides of protein — of the very same matter with which the blood-corpuscles become invested. For this reason the form assumed by the two layers on both sides of the little flat body — the corpuscle — is determined by the buoyancy of the blood. Resulting from this tendency to contract and become bi-concave is so strong, that the central portion of the clot becomes entirely depressed. In this form the corpuscles reflect a great deal more light than when, in consequence of the recovery of the buoyant mass in the capillaries, they have a less bi-concave form.

From four analyses of the blood of horses, Simon deduces the following rule regarding the chemical differences of arterial and venous blood. 'Arterial blood contains less solid residue generally than venous blood; it contains less fat, less albumen, less hematin, less extractive matter and salts, than venous blood. The blood-corpuscles of arterial blood contain less coloring matter than those of venous blood. 'The arterial blood was taken from the carotids, and the venous from the jugulars.

Composition of healthy human venous Blood.—In a medical point of view, the composition of venous blood is the more interesting, because it is from the veins that blood is almost always taken in disease, and because venous blood can naturally only be compared with venous blood for the purpose of securing correct chemical conclusions. The following table represents the mean composition of human venous blood without reference to sex. —

| Component | Water 762-725 | Cholesterol 205-169 | Fibrin 2-104 | Fat 2-346 | Albumen 76-650 | Hematin 103-920 | Extractive matters and salts 12 012 |

100 parts of blood-corpuscles contained 6-7 of hematin. Hence the blood contains about 20 per cent. of solid constituents, and 0-2 per cent. of fibrin, and about an equal quantity of fat; the blood-corpuscles considerably exceed the albumen in quantity, and contain about 5 or 6 per cent. of colouring matter.

Lymph and Chyle.—Closely allied to the blood are the

lymph and chyle. These fluids have only recently been submitted to correct chemical examination. In Simon's 'Chemistry' the reader will find recent analyses of the former by Marchand and Colberg, L'Heretier, Rees, and Nasse; and of the latter by Simon, Rees, and Nasse.

From a consideration of the blood we naturally turn to that of the various secretions yielded by it.

The saliva has been analysed by Simon, L'Heretier, and Wright. The following is Dr. Wright's account of healthy saliva: 'It is a yellow fluid resembling aqueous prussic acid, and in a healthy subject is always secreted after a meal than during fasting. Healthy saliva has mostly the specific gravity of 1007-9. When above 1010 or below 1008 it may be considered morbid. Healthy saliva in either alkaline or neutral, or even acid, state. The belief in the existence of the principle termed ptyalin, although it separates from the saliva by a new process, which is to pass saliva through ordinary filtering paper, and after filtration have been accomplished, the residue with sulphuric ether: the ethereal solution contains a fatty acid and ptyalin. It is to be allowed to evaporate spontaneously, and the residue left by evaporation is to be placed upon a filter and acted on by distilled water, which dissolves the ptyalin and leaves the fatty acid.' On evaporating this solution to dryness the ptyalin will be obtained in a pure state.

In relation to the presence of sulfo-cyanogen Wright remarks that it is a constant ingredient of the saliva. The proportion, he observes, is temporarily augmented by local stimulation of the salivary glands, as by smoking, chewing alcohologues, &c. It is also increased by the internal use of prussic acid and salts of cyanogen, and remarkably so by the use of sulphur. The occurrence of this substance in the saliva is equally interesting in a physiological and in a medico-legal point of view. The circumstance that it forms with the periodate of yellow dye a brilliant yellow-red coloration, of which the analysis of iron must not be overlooked in examining the stomach in a case of suspected poisoning by opium. L'Heretier has recorded the mean of 10 analyses of the saliva of healthy persons — made while fasting.

Water 980-5 Organic matter 12-6 Inorganic matter 0-9

The ptyalin formed 2-5 of the 12-6 parts of organic matter.

Mialhe has recently (April, 1845) announced the discovery in the saliva of an active principle analogous in its physical and chemical characters to diastase. It is solid, white or greyish white, amorphous, insoluble in alcohol, but soluble in water and in weak spirit. The directions for obtaining it are the following: filter saliva and treat it with five or six times its weight of absolute alcohol, adding it as long as any precipitate occurs. This animal diastase falls in white flakes, which when washed with a little alcohol, the 100 parts of the dry residue were dissolved in 100 of water, to which 10 of hydro—
cholic acid had been added. Allowing evaporation at a moderate temperature to proceed, it was observed that a dark green oil collected on the surface, while at the same time the fluid became turbid. On removing the oil and allowing the fluid to rest for several days, a precipitate of a green deposit. This dark green bitter precipitate is Demarçay’s cholic acid, and is regarded by him as consisting of nine-tenths of the solid constituents of the bile. It is still mixed with muriatic acid, chol(e)tin, pigment, &c. After their removal it forms a yellow spongy mass, which rapidly absorbs oxygen from the atmosphere, is very bitter, slightly soluble in ether, soluble in water, and very soluble in alcohol. The characteristic property of it is the addition of a solution of soda to an alcoholic solution of cholic acid, and then passing a current of carbonic acid through it to remove the excess of soda, possesses all the characters of ox bile: it yields on evaporation a brown resinous mass, and is soluble in water and in alcohol.

When cholic acid is boiled with hydrochloric acid it yields ammonia, taurine (see Taurin, P. C), chol(e)tid acid; the latter being insoluble is decomposed. The formulae usually assigned to cholic acid, taurine, and chol(e)tid acid are, \( \text{C}_5\text{H}_9\text{N}_2\text{O}_3\text{S}_2 \); since it contains no less than 26-6 per cent. of sulphur which had been previously altogether overlooked (Liebig and Willich, in Annalen der Physik, vol. 12, p. 245, 1846). Hence there can be no doubt that the formula for cholic acid also requires considerable modification. For further information on the recent history of the chemistry of the bile we must refer to Duesberg's 'Reports on the Progress of Animal Chemistry,' in Rankin's 'Half yearly Abstract of the Medical Sciences,' vol. ii. and iii.; and Plater's 'Über die Natur und den Nuten der Galle,' Heidelberg, 1845. The following description of the microscopical and chemical character of healthy human bile is condensed from a series of papers on the subject by Frerichs (Hannovers. Med. Ann., 1. and iii., 1845).

In colour it is always a deep brown, but when seen in thin layers it has a brownish-yellow tint. It is very fluid, being viscous only in newborn infants. The specific gravity varies from 1028 to 1040. On examining with the microscope bile from the gall-bladder, with which, of course, a certain amount of mucus is mixed, there are observed:—1. Transparent or greyish round vesicles, about the 700th of a line in diameter; they disappear on the addition of alcohol or ether, and are removed by filtration. 2. Conical yellow bodies, about the 140th of a line in length, and about the 300th or 400th of a line in breadth, apparently devoid of nuclei; these are epithelial cells, either cast out of the flakes, or irregular dark granules, which disappear on the addition of a solution of potash, apparently pigment cells. 4. Occasionally minute crystals of chol(e)tin, occurring as colourless rhombic talc-like crystals.

The chemical characters are shown in the two following analyses. The bile in these cases was obtained from healthy men, killed by severe accidents:—

Plater has recently succeeded in obtaining cholic acid and chol(e)tic acid of soda in a crystalline form. This is a mere excrementitious fluid, intended to remove effects of the bile, but that it is secretion essential to the animal economy, was rendered almost certain by the experiments of Berzier, Teyler, and Schlösser, which showed that the human faces contained much too small a quantity of a substance producible by the body, as that it is evacuated in this manner. Further proof that the bile is absorbed and not excreted is afforded by an examination, made by Enderlein, of the ash yielded by the contents of the different portions of the intestinal canal of a hare. He found that the ash from the contents of the duodenum alone effervesced on the addition of an acid, thus showing that the choleaste of soda (which yields the carboatomic incineration) is absorbed before reaching the jejunum. Schwann has made experiments to the same opinion beyond a doubt, by a series of well-derivated experiments on dogs. He tied the ductus choledochus, and at the same time formaldehyde, in the gall-bladder, by which the bile escaped externally. His observations are as follows:—first, that when the bile does not get into the bowel its absence is generally perceptible in dogs about the third day by a marked diminution in weight; and, secondly, that besides the channel for the conveying of bile, there is re-established symptoms of deficient nutrition, wasting, debility, &c. Hence, and death is the ultimate consequence.

The chemistry of this subject is still very unsettled; it has been recently made the object of especial study by Bloudot, Bernard and Berrewil, Molens, and Dr. R. D. Thompson, who have obtained very contradictory results.

The mud has been recently examined by Simon, Cream, and Dunna. The reader will find a copious account of the chemistry of this secretion in Simon's 'Animal Chemistry,' vol. iii. pp. 49-69.

The urine has, since the publication of the article Uzmann, P. C., been made an object of especial investigation by Liebig. The most important fact that has been discovered is that hippuric acid is, although in small quantity, a constant ingredient of this secretion. The importance of this fact is its tendency to suggest that the urine and hippuric acids possess of combining with the potash or soda of the alkaline phosphates, and thus forming hippurate.

The brief space necessarily allotted to this article has rendered it imperative on us to omit the consideration of many points of very high physiological importance. For further information on the subjects contained in the preceding pages we must refer to the following works:

On the Structure of Animal Tissues—Hene’s Algemeine Anatomie; the article 'Tissues (Gewebe) in Wagner’s Handwörterbuch der Physiologie, Böman and Tedde’s Physiological Anatomy and Physiology; the works of Dr. Carpenter; Gooden’s Anatomical and Physiological Observations; the articles 'Muscles, 'Muscle,' and 'Osseous Tissue;' in Todd’s Cyclopaedia of Anatomy and Physiology; and Mr. Tomes’s Lectures on Dental Surgery in the Medical Gazette for 1845-6. The best account in the English language of vegetable tissues is given in Hensley’s Structural and Physiological Botany.

On the Chemical Department of this article we must refer to Simon’s 'Animal Chemistry;' to Dr. Day’s Reports on the Progress of Physiological and Pathological Chemistry, in Rankin’s 'Half yearly Abstract of the Medical Sciences;' to Liebig’s 'Animal Chemistry,' translated by Gregory; to Muller’s 'Versuch einer Allgemeinen Physiologischen Chemie;' to Lehmann’s 'Lehrbuch der Physiologischen Chemie;' and to L’Heritier’s ‘Traité de Chimie Pathologique.’

TLEMSN. [ALGERS, P. C., p. 330.]

TOD, JAMES, Lieutenant-Colonel in the service of the East India Company, was born in 1789, in England, but educated in Scotland. He went out to India in 1806, and obtained a commission in the 2nd Bengal European regiment; thence he volunteered for the Mowzcaus, was transferred to the marines, served as a marine on board the Mornings, and, in 1808, when in the subordinate service at Gwalior, in Hindostan, was attached, under his friend Mr. Graeme Mercer, to the embassy sent at the close of the Marattas war to the camp of Sindia in Mowar, where he remained from the springing of 1806. Rajpoottana, of which Mowar is one of the states, thenceforward became the scene of his official labours, as well as of the geographical, historical, and antiquarian investigations by which he distinguished himself. He went back to England in 1817, and was presented to the Marquis of Hastings, then governor-general of India, and it was of great use in forming the plan of operations in 1817, the previous maps of the country having been very imperfect and erroneous.

The maps so far as they intersected the entire control of five of the states which had just then placed themselves under British protection, Mowar, Marwar, Jassimulre, Kotah, and Boondee. The results of
his investigations into the geography, history, and antiquities of Rajputana are given in his 'Annals of Rajasthan.'

In 1852, the impaired state of his health rendered it necessary that he should return to the more congenial climate of his native country. Previously however to his departure from India, he made a circuit of nearly the whole of Rajputana which he completed at the close of 1822, and in the beginning of 1823 he sailed from Bombay, and arrived safely in England.

After his return to England his time was chiefly devoted to literary pursuits. He often acted as a librarian to the Royal Asiatic Society. In 1834 he went to the Continent for the relief of a complaint in the chest, and remained abroad twelve months. He returned to England in September, 1835. When he arrived his house was occupied with 'Travels in Western India,' the result of the journey which he made previous to his return to England, and especially his observations in Gujterat. The last chapters of the work were written in October, 1835, while residing with his mother in Hampshire, and the MS. is said to have been left nearly fit for publication except filling up a few blanks and the completion of the engravings; but it has not yet been published.

On the 16th of November, 1835, while transacting business with his bankers in London, he had an attack of apoplexy and lay without consciousness for twenty-seven hours. He died November 17, 1835, at the age of fifty-three. He left a widow, the former Miss Flutterby, and a family.

Bishop Heber, who travelled through Mewar and the adjoining Rajput states, in 1825, on his way to Gujerat, bears testimony to the affection and respect borne to Colonel Tod by the country people. He says, 'After a sort of travelling through which the bishop passed, he says, 'Here and in our subsequent stages we were continually asked by the cutwals, &c., after Tod Sahib (Captain Tod), whether his health was better since he returned to England, and whether there was any chance of seeing him again. On being told it was not likely, they all expressed much regret, saying that the country had never known quiet till he came among them, and that its people rich or poor, except thieves and Pindars, loved him. He, in fact, Mr. Smith told me, loved the people of this country, and understood their language and manners in a very unusual degree.' Bheelwar, a commercial town, which had contained 12,000 families, had been nearly ruined by the depredations of the Maharratts at the time when Colonel Tod was appointed political agent. He set himself to restore it, and in less than a year there were seven hundred prosperous and peaceful families in it. Colonel Tod, in a letter to a friend, says, 'Regarding Bheelwar, the work of my hands, in February, 1818, there was not a dog in it; in 1822 I left 9000 houses, of which 1200 were bankers and merchants.

An entire street, paved, was built under my directions, and with my means. The merchants from Calcutta, Jessulmer, Delhi, Surat, from every mart in India, had their correspondents, and in fact it was becoming the chief mart of Rajasthan. The people a thousand times repaired the damages they had received, and the roads were repaired for the first time. The people had been kept in the state of preparatory poverty.

Bishop Heber, after describing the prosperous state in which he found the town in 1825, says, 'The place had been entirely ruined by Jumahoo Khan, and desolated by all his predecessors.' Captain Tod then introduced the Bheels to some of our established measures for encouraging the owners of land to return, and foreign merchants to settle. He himself drew up a code of regulations for them, and obtained them an immunity from taxes for a certain number of years, and sent them patterns of different articles of English manufacture for their imitation. He also gave money liberally to the beautifying of their town. In short, as one of the merchants who called on me said, 'It ought to be called Todgir, but there is no need, for we shall never forget him.'

The 'Annals of Rajasthan' were published in London, in 2 vols., 12mo., 1826, and 1827. Bishop Heber's Narrative of a Journey through the Upper Provinces of India, 1824, 1825, and 1826, is an excellent work. It周淑教 was educated at Hertford College, Oxford, where he proceeded M.A. in 1786.

He became a minor canon of Canterbury Cathedral soon after his graduation. In 1792 he was appointed by the Dean and Chapter of Canterbury to the vicarage of Milton, near that city; and some years after, by the same body, to the rectory of Allhallows, Lombard Street, London, on which he fixed his residence in the metropolis. In November, 1803, he was appointed, by the Archbishop, Keeper of the Manuscripts at Lambeth. In 1820 he was withdrawn from London, by being presented by the Earl of Bridgewater to the rectory of Settrington, in Yorkshire, of the value of 1046; in 1825, was appointed to the see of Hildesheim; and, finally, in 1832 he was appointed Archbishop of Cleveland.

His first work published was Some Account of the Deans of Canterbury, from the new foundation of the Church by Henry VIII., 8vo., 1788. This was followed by an edition of Milton's 'Masque of Comus,' with notes and illustrations, from a manuscript belonging to the Dean of Bridges, 1798; 'The Poetical Works of John Milton,' with notes and life, 6 vols., 8vo., 1801, for which he received 2000l. from the booksellers, and of which there was a second edition in 1817; 'The Works of Edmund Spenser,' with notes and a Life, 8 vols. 8vo., 1806, reprinted in 1845; 'Illustrations of the Lives and Writings of John Gower and Geoffrey Chaucer,' 8vo., 1810; 'A Catalogue of the Archi-eapiscopal Manuscripts in the Library at Lambeth Palace,' vol. 1829 (100 copies privately printed); a new edition of Dr. Johnson's Dictionary of the English Language, with corrections and additions, 4 vols. 4to., 1814, &c., and again in 3 vols. 4to., 1827; 'The History of the Collected Works of Daniel Defoe' for the Earl of Bridgewater); 'Original Sin, Free Will, Redemption, Faith, Good Works, and Universal Redemption, as maintained in certain Declarations of our Reformers,' &c.; and in 1839, 'A Supplement to the 'Psalms and Translators of the Bible' (in reference to Bellamy's new translation), 8vo., 1819; 'Observations on the Metrical Version of the Psalms, by Sternhold, Hopkins, and others,' 1826; 'Memoir of the Life and Writings of the Right Rev. Brian Walton, Bishop of Chester,' 2 vols. 8vo., 1821; 'An Account of Greek Manuscripts of the late Professor Carlyle, now at Lambeth,' 8vo., 1829 (privately printed); a new edition of the 'Doctrine of the Sacrament,' 8vo., 1825, with a Vindication of Cranmer, reprinted in 12mo. in 1826; 'A Letter to the Archbishop of Canterbury, concerning the Authorship of Iona Basiliks,' 8vo., 1837; 'Bishop Gauden the Author of Iona Basiliks' further shown, in answer to Dr. W. Watson,' 8vo., 1839; 'Life of Archbishop Cranmer,' 2 vols. 8vo., 1831 (an enlargement of the 'Vindication'); 'Authentic Account of our Authorized Version of the Bible,' 12mo., Malton, 1834. We have omitted a few theological papers of inferior merit, and the writings of the period in which he was also, in the early part of his literary career, a frequent contributor to the 'Gentleman's Magazine;' and he is stated in Hasted's History of Kent, to have assisted largely in the preparation of the 'History of England, as far as respects Archbishop Cranmer,' 8vo., 1827; 'Bishop Gauden the Author of Iona Basiliks' further shown; in answer to Dr. W. Watson,' 8vo., 1839; 'Life of Archbishop Cranmer,' 2 vols. 8vo., 1831 (an enlargement of the 'Vindication'); 'Authentic Account of our Authorized Version of the Bible,' 12mo., Malton, 1834. We have omitted a few theological papers of inferior merit, and the writings of the period in which he was also, in the early part of his literary career, a frequent contributor to the 'Gentleman's Magazine;' and he is stated in Hasted's History of Kent, to have assisted largely in the preparation of the

Adarcheson Todd, who was a Chaplain in Ordinary to her Majesty, died at Settrington, on the 24th of December, 1845. From his will, an abstract of which is given in the 'Gentleman's Magazine' for June, 1846, he appears to have left several daughters.

Adarcheson Todd, though the editor of Milton and Spencer, had no pretensions to either poetical talent or poetical taste; nor was even his acquaintance with our old poetry, or with our old literature in general, very extensive or intimate. His annotations, accordingly, are rather dry. At the same time, if they do not overflow with much variety of knowledge, and rarely display any remarkable ingenuity, they do not annoy the reader by any kind of superfluous disquisition. He is certainly not a very animated narrator; but his facts may generally be depended on. In 1822, as most of his notes, perhaps, have been rendered in the field of bibliography.

(Memoir in Gentleman's Magazine for March, 1846.)

TOFIELDIA, a genus of plants belonging to the natural order Gentianaceae. It contains but one species, known as T. palustris, the only British species, has peduncles naked at the base, and is divided into two varieties. The flower buds are from 4 to 8 inches high, the leaves sword-shaped, about 2 inches long, in 2-ranked radical tufts. The flowers are in a dense spike, at first sepalis, afterwards slightly stalked with a slight lobe of the base of the stalk, but none under the perianth.

TOMPAG. [SHJIT-BUILDING, P. C.]

TOPES. [AFRNICAN. P. C. N.]

TORDYLIUM (Cody. wounded or Discourages. S. 5), a genus of plants belonging to the natural order Umbelliferae. The calyx has 5 teeth; the petals are obvate, emarginated at the base, and rather small; the stamens are white, and laterally compressed; the carpels with prickly primary ridges, the secondary hidden by the numerous prickles which occupy the interstices; the flowers white, those in the side of the umbel unequal and sterile.

T. anthracis has bipinnate leaves, the leaflets ovate, lanceolate, inciso-serrate; the umbels on long peduncles, the leaves of the involucre oval-shaped, the fruit covered with bristles, the outer red, the inner white; it is native of Europe and Caucasia, and is plentiful in Britain.

T. infesta has an erect many-branched stem, the leaves bipinnate, the leaflets deeply cut, ovate, lanceolate. The fruit is densely prickly, the flowers small and reddish. It is found on fields and waste places in Europe and Great Britain.

T. pseudo has nearly sessile dense umbels, the outer carpels with hooked bristles, the inner generally covered with dense whitish shining granulations; the lower leaves are bipinnate, the upper ones pinnate; the leaflets deeply, narrowly, and anastomosing; it is native of Europe and the Levant, and is plentiful in Britain.

The seeds only require to be sown in the open ground.

TORTOISE-SHELL. This beautiful substance, or at least the best kind of the material which goes under the name, is procured from a marine tortoise called the Hawk-bill, or Témoine (P. C. N., [Harv.]. 76, 77], the Latin name of which is derived from the mode in which the scales upon its back are arranged, overlapping one another like the tiles upon the roof of a house, one kind of which were called by the Romans intestices. In most other tortoises the several scales of which their covering is composed adhere to one another by their edges, like inlaid work. Each animal furnishes thirteen principal plates, five along the centre of the back, and four on each side; and twenty-five smaller scales or plates, which constitute the margin of the shell. The size and thickness of the plates, observes Mr. Aikin, are more or less variable; and the Tortoise-shell, in the 'Transactions' of the Society of Arts, vol. iii., part ii., pp. 343-347, depend on the magnitude and age of the animal, a fresh layer being produced every year; and at the margin of the large plates may be seen distinctly the edges of the layers as they thin off in succession. Sometimes, however, he adds, large plates are met with, so thin as to consist, apparently, of only a single layer; and he observes that some of the dresses seem to be without effect and to be mere stipples. But in those thin plates are the produce of full-grown tortoises that have been stripped of their plates the year before, either purposely or by accident. Herring plates which constitute true tortoise-shell are separated from the common tortoise-shell by the large size of the shell or covering of the animal by the application of heat; the whole shell being commonly placed over a fire until the plates begin to start from the bone, and the separation being completed by the aid of a slender knife. The shell varies much in value, being frequently injured by barnacles, fragments, and other shell-fish, adhering to the tortoise while alive, and interfering with the preparation of the shell where play attack themselves. Occasionally plates of a uniform yellow colour are met with, and such, Mr. Aikin states, are in great request among the Spanish ladies, who require at least twice as much for a comb of plain tortoise-shell as for a mortice comb. The belly-plates of the tortoise are yellow, and sometimes they are found sufficiently clear for use.

The mode of converting tortoise-shell so nearly resembles the working of horn, described on pages 40 and 47 of this volume, as to need but little further notice; but owing to the very high value of the material (about three guineas per lb. was the price of fine shell when Aikin wrote in 1839), it is economised as much as possible. Before working the shell needs to be softened or tempered, which is usually done by dipping it for three or four minutes, or longer, if it is very thick and brittle, into boiling water. It should have a little salt mixed with it, because pure water absorbs much of the colour. Too much salt however renders the shell brittle; and too long boiling injures it by turning it nearly white, and covering it with opaque white film. According to Holstamphi, in whose work on 'Turning and Mechanical Manipulation,' vol. i., pp. 198-195, is a very full account of the handling of the tortoise-shell into various articles of taste and utility, some manufacturers flatten and temper their shells with hot flat irons, similar to those used by laundresses; the tortoise-shell is made somewhat slender, and, in the course of the operation, frequently moistened with water to prevent scorching. Holstamphi remarks that generally the less the shell is heated and pulled about the better, because from its apparent want of grain or fibre it is so to become brittle. Being also less fusible than horn, tortoise-shell cannot be made soft enough to be moulded without some injury to the colour; and accordingly, Aikin states, the manufacturers, at least in England, never attempt to produce tortoise-shell combs or other ornamented work, by the use of hot water to soften.

Such work is produced by pasting a piece of paper over the tortoise-shell, drawing the pattern upon it, cutting it out, with drills and fine saws, and, after the paper has been removed by steeping in cold water, finishing the ornaments with the graver. The cutting or parting of the teeth of combs by machinery is described under Coma, P. C. S., p. 185, but we may here mention another mode which is occasionally followed, and which illustrates the convenience arising from the flexibility of the material when warmed. A piece of tortoise-shell large enough to make two combs, with their teeth interlaced, or bent over in the same manner as the length of the teeth, to such a degree of convexity that they may be cut with a straight bow-saw without cutting through either of the edges of the pieces of shell, which are required to form the top or bottom of the portions of the comb, is flattened and the ends or points of the teeth are separated with a narrow chisel or prickcr, after which the combs are finished with files and scrapers, and bent to any required form. The same substance is also used for the same purpose in making the frames of earrings, which are usually formed of narrow strips of shell in which a brass or oval apertures, by the insertion of tapering strips of the required shape. The same yielding or flexible property is made use of in the manufacture of boxes; a round disc of shell being gradually forced by means of a mallet into the form of a circular box with upright sides. The union of two or more pieces of shell may be effected by carefully scraping the edges that are to overlap, in order to render them as smooth as possible from grease, even such as might arise from being touched by the hand, softening them in hot water, pressing them together with hot flat tongs, and then plunging the joint into cold water. In veneering with tortoise-shell, by which the work may be produced, it is usual to apply fish-glue, mixed with lamp-black, varnish, green, white, or other colouring matter, at the back of the shell, both to help it to stick, and to ensure permanency of the shell to the wooden foundation. In making knife-handles and other ornamental work metallic foils are put beneath the tortoise-shell, and the whole is fastened by an adhesive. Aikin refers to the luxurious taste of the Romans of the Anglian age for conches and other articles of furniture.

wended or in aid with tortoise-shell; and in Dr. Smith's
 Dictionary of Greek and Roman Antiquities," p. 585, it is
 stated that the name is sometimes called by Greek writers
 Ξανθός or ξάνθος, and in Latin testudo, because it was occa-
sionally made of tortoise-shell.

TOWNLEY, JAMES, REVEREND, the eldest son of
a well-known writer of the eighteenth century, was born
at Merchant Tailor's School, elected thence to St. John's
College, Oxford, and took orders. After having held two
lectureships in London, he was appointed, through the
interest of Lord Byron, to the living of St. Bennet's,
Gracechurch Street. Afterwards he was grammar-master in
Christ's Hospital, and in 1799 was appointed head master
of Merchant Tailor's School, and held that office till his
death in 1798, which happened soon after he had been
appointed to a living in Wales. He is said to have been
adored as a preacher: and some single sermons of his are
in print. But he is chiefly known on account of his intimacy
with Hogarth and Garrick. To the former he and Morell gave
material assistance in the composition of his 'Analysis of
Beauty,' and he got the credit of having much assisted the
latter in his dramatic works. The popular fancies of 'High
Life Below Stairs,' first played in 1759, was at length owned
by him. He was also the author of two other farces, which were
unsuccessful; but one of them, 'False Concord,' contains
beasts of various names, which were borne to be in a Glennis
and Colman's comedy of 'The Clandestine Marriage.'

The closeness of Townley's connexion with Garrick is further
evidenced by the fact that he received from Garrick, and held
Sweeney's comedy is not to be

TOXOTES, a genus of Acanthoperichous fishes of the
family Squamipennes, the species of which are remarkable
for having the power of spinning jet stream of water even to a
height of three or four feet with such accuracy of aim as to
bring down the insects upon which they feed from the aquatic
plants frequented by their prey.

TRACHILDES, the fourth family of heteromorphous
Coleoptera in Larratelle's arrangement of insects. The head
is more or less triangular or pedicel, and cannot be
retracted. They have soft bodies, smooth flexible elytra, often
showing the outlines of the segments, which are not hidden
on leaves and flowers. Many of them simulate death when
seized. Lagria, Pyrochroa, Mordella, Notoxus, Floria, and
Malery are types of tribes in this family.

TRADER. [Bankrupt. P. C.]

TRANSFER OF REAL PROPERTY. During the last
nine years various statutes have been passed for the purpose
of facilitating the transfer of Real Property.

The first of these was one passed in the 4th & 5th of Victo
ria, intituled 'An Act for rendering a Release as effectual
by the sealing of a Freehold Estate as a Lease and Release
by the same parties.' It enacted that every deed or instru
ment of release of a freehold estate executed after the 15th
of May, 1841, and expressed to be in pursuance of the Act,
should be established in all respects, as if the parties thereto had also executed the usual lease for a
year, providing at the same time that such release should
be subject to the same stamp duty as the lease and release
whereby a freehold estate is liable to under the Acts relating to the
Stamp Duties,

In consequence of the terms used in this Act, it was thought
necessary that all releases made under it should re
force the title in order to give them full effect. To obviate
the difficulties often arising from the loss of the lease for a
year, it was enacted by the second section, that the rectal
or mention of a lease for a year in a release executed before the
passing of this Act should be evidence of the execution of
such a lease for a year.

The next Act on the subject was the 7th & 8th Vict., c. 76,
intituled 'An Act to simplify the Transfer of Property.'
This Act having been found in many respects objectionable,
it was in the following year repealed by the 8th & 9th Vict.,
c. 106, whereby several of the provisions of the former have been retained, and which contains an improved formula.

This Act is intituled 'An Act to amend the Law of Real Property,' and, as its provisions will have a great effect upon the Transfer as well as the Law of Real Property, it will be necessary to consider them at large.

After repealing all the clauses of the former Act from the 1st of October, 1845, except those which related to contingent
remainders, which were repealed as from the commencement
of the former Act, it provides: That after the 1st of October,
to Remainder, P. C. The practical effect of this section will be the omission in settlements of the limitations to trustees for life without remainder. By sect. 9, where the revision on a lease shall, after the 1st October, 1845, be surrendered or merged, the estate which shall for the time being consist of a leasehold estate vested right to the estate, for the purpose of preserving the incidents to and obligations on the same revision, which, for the surrender or merger, would have subsisted, be confirmed by the same or other description of this section is to do away with the rule that the covenants of and remedies against a lessee, and the obligations on the lessor, being incident to the immediate revision, cease as regards the land on the merger of that revision in another estate.

In the 8 & 9 of Vict. two acts were passed which had for their object the reducing the length of conveyances of property and leases. The first, the 8 & 9 Vict. c. 119, is entitled 'An Act to facilitate the Conveyance of Real Property;' and the second, the 8 & 9 Vict. c. 124, 'An Act to facilitate the granting of certain Leases.' The provisions of the two acts are analogous, and their place is that of providing, that where the words in the first column of the schedule attached to the act are used in a deed, they are to have the same effect as if the words in the second column had been employed. But an omission here lies in the short clause, and in the second the long covenant for which the first may be substituted. The acts also contain provisions for making slight alterations in the wording of clauses according to the case. It seems doubtful whether these acts will be of much practical application.

All the acts here considered relate to England and Ireland, but not to Scotland.

TRANSPORT, RAILWAY. In an article intended to be supplementary to that given under RAILWAY, P.C., pp. 245-257, and to treat especially upon matters which have risen into importance during the six years that have elapsed since that article was written, many topics which seem to claim attention must be passed over, or treated very briefly. Except in the simply historical portion of the subject, almost every part of the present article is referred to the provision as to what something might be said indicative of the rapid progress of mechanical improvement, or of the results of extended experience; but our attention must be confined to a few only of the more important points relating to railway legislation, and to the construction, working, and management of railways, together with statistical notices of the progress of the railway system in the United Kingdom, whence it is rapidly extending over the whole face of Europe, and of the civilized world. To facilitate reference we shall, as far as the natural dependence of one subject upon another will allow, follow the order of arrangement adopted in the article RAILWAY, so that the reader may see at a glance the connection of the original and the supplemental matter. The principal deviations from this course are in the bringing together, under the general head of 'Railway Companies,' the matters relating to the obtaining of railway acts, originally noticed under RAILWAY, pp. 251, 252, and such as relate to railway control, taxation, &c., which were noticed in pp. 260, 261 of that article; and in the incidental notice in connection with the important question of gauge, of various matters relating to general principles of railway construction, working, and management.

Railway Legislation.—The growth of Railway travelling in this country has been so sudden, and its consequences, in relation to the interests of the public, were so little foreseen at its commencement, that until very recently it has advanced without control, and, it may be said, almost without the note of the Government. There are two opposite principles of administrative policy which may be pursued in reference to undertakings of public utility. By one all such works are executed either directly by the government or under government superintendence; by the other they are the result of private enterprise, and government has no further concern with them than to give or withhold the legal powers necessary for their execution. It is not our purpose to discuss whether the spirit of commercial enterprise very active, the former principle is often essential for the promotion of public works, and it has accordingly been adopted by the governments of France, Belgium, and the United States, and in the works of the mines and resources of capitalists are so remarkable as in England, no encouragement is needed from the government, and its interference is required only for the protection of public interest. The circumstances of this country, therefore, would naturally have dictated the policy of permitting the employment of capital in the undertaking; but, in the event of it being done as much as possible; and our free institutions, and the generally passive character of our government, have favoured politically a principle which would have the effect of making the expedient. It may be doubted, indeed, whether this principle would have been carried too far; and whether capital would not have been invested more beneficially under a surer and more provident system of legislation. The following is a sketch of the proceedings which have been necessary for carrying out a scheme of railway communication. The parties who have planned it obtain subscriptions to the undertaking, and having undertaken the surveys and satisfied themselves of the profitable character of the speculation, they determine to apply for an Act of Parliament to incorporate a company for executing the works, and to give them the powers required for that purpose. The most important power to be obtained is that of taking lands and houses without the consent of the parties interested in them; and in the early period of railway legislation, the only opposition encountered by railway companies was that of the landowners, who were either unwilling to sell their land or dissatisfied with the price which had been offered them. If this opposition was overcoons or conciliated, the bill was passed through Parliament; but if not, the company would have power to acquire the lands by the purchase of them. But there were no competing lines, no means were taken by Parliament to inquire whether the line was the best that could have been suggested for the district through which it was intended to pass; but evidence was taken that the bill was given the slack was held to establish the public utility of the undertaking; and it was authorised. The executive government took no part in the investigations, and Parliament, on the support of members locally interested can scarcely be said to have inquired into the merits of lines except when an inquiry was forced upon them by the opposition of private parties. Little or no security was taken for the public interests, and so little was the character of railway communication understood, that in fixing the tolls and charges, parliament at first named a maximum for the tolls, as in the case of canals, but imposed no limitation upon the charges for the conveyance of goods and passengers. As the companies undertook the entire traffic of their own lines, no tolls were payable, and thus the maximum, which was intended for the security of the public, was wholly imperceptive. This oversight has since been rectified, and every railway act of 1845 and 1846, for a new line or for the amendment of acts, under which existing lines were constructed, contains a clause which reserves to Parliament the right of revising the fares and charges; and in most of the recent acts the maximum charges are moderate. In 1836 committees were required to give more detailed reports concerning the bills committed to them, and to make out their proceedings upon the original papers in a form rather than in substance. In 1839 the constitution of the committee was improved by the admissibility of ' selected members,' who were not locally interested; and in 1844, the committees have been composed exclusively of members who have had no local interest in the lines referred to their consideration. But however these tribunals may have been improved, the same system of legislation has practically prevailed. Unopposed lines have, almost without exception, been sanctioned upon the ex parte evidence of the promoters; and opposed lines have been granted or refused according to the relative wealth, influence or perseverance of the contending parties. It is undeniable that more vigilance ought to have been exercised in investigating the merits of lines, and in securing the best terms for the public which were consistent with justice and fairness; while, on the other hand, the promoters of railways ought to have been protected against the ruinous waste of capital which has been occasioned by vacillating forms of procedure, and by ill-regulated and too often incompetent tribunals.

But notwithstanding admitted defects in the system of railway legislation, and the abuses which have arisen from it, the principle of allowing free competition to the spirit of enterprise and capital has been eminently successful, and more railways have been constructed in the last fifteen years, and more science and skill have been devoted to their improvement, than a government could have called for in half a century. Nor have the public interests otherwise suffered so materially as might have been anticipated; for the conditions, for the public good, which might have been made the
subject of express transportation, have in great measure been secured by the operation of the same principle. The charges upon goods and passengers, for example, which might have been brought to 50 per cent. and strictly, have already continued in being for some years, and are undoubtedly necessary for the proper working of the system. The provisions of the act were mainly directed to the establishment of public safety; but in 1844 a more important act (7 & 8 Vict. c. 85) was passed with a view to secure, as far as possible, the interests of the public from being sacrificed to the selfish, profit-making desires of those companies which had been granted special privileges by parliament, in perpetuity, to railways and the like. The act secured the portion of this revenue, and upon such conditions as may be contract for by the secretary at war.

The provisions of the act were mainly directed to the establishment of public safety; but in 1844 a more important act (7 & 8 Vict. c. 85) was passed with a view to secure, as far as possible, the interests of the public from being sacrificed to the selfish, profit-making desires of those companies which had been granted special privileges by parliament, in perpetuity, to railways and the like. The act secured the portion of this revenue, and upon such conditions as may be contract for by the secretary at war.

Annual profits divable upon the paid-up capital shall have exceeded 10 per cent. upon the average of the three preceding years, the Treasury may revise the scale of tolls and charges, and charge such tariffs to profits to 10 per cent.; with a guarantee, however, that 10 per cent. should be made good to the company, and that without their consent no further revision of their charges should be made for twenty-five years. But at the expiration of the twenty-one years, the Treasury may purchase any such railway, in the name and on behalf of her Majesty, paying within three months' notice, and on the basis of 25 years' purchase of the annual profits estimated on the average of the three preceding years, subject to arbitration however, in particular cases, and to certain exceptions. And in order to effect these provisions, full powers are given to examine all the books and accounts of the companies for three years preceding the time at which the tolls may be revised or the railway purchased. For reasons which are well explained in the second report of the Railway Committee of 1846, it is doubtful if these prospective securities will ever be available; but immediate advantages were also secured to travellers and to the government.

In order to ensure the means of travelling by railway at moderate fares, in carriages protected from the weather, it was enacted that every railway company incorporated in the session of 1844, and within which a large portion of the whole traffic of the country is rapidly being absorbed in railway communication, and so enormous a public interest needs the utmost care of the government. To guard the public interests, it was provided that no carriage or conveyance is quite entitled as regards the public interest, or as regards the freedom of capital.

Having stated these general principles in reference to railway legislation, we may proceed to a brief analysis of the various measures which have been passed, from time to time, for the supervision of railways and for other purposes connected with the general administration of railway affairs. The objects for which they were passed are not always analogous, but it will be convenient to offer a consecutive view of them as, however imperfect they may be, they, constitute, in effect, our whole railway code.

The first step towards a control of railways by the government was taken in 1840, when an act was passed to place them under the supervision of the Board of Trade (3 & 4 Vict. s. 97). By this act it was provided, that no railway should be opened until a month's notice had been given to the Board of Trade; that returns should be made by all railway companies of their traffic, of accidents, and of their tolls, rates, and charges; that the Board of Trade should be authorized to appoint inspectors, and to take any by-law should be submitted to the Board, which may disallow them. These and other matters provided for by this act, at once disturbed the independence under which the railway system had hitherto grown up, and placed all railway companies under the immediate supervision, and, in some degree, under the control of government.

By the act 5 & 6 Vict. c. 55, power was given to the Board of Trade to order, in the opening of stations, and the setting of lights, and in general, as not considered safe by their inspectors: notice of accidents attended with serious personal injury was to be given to the Board within forty-eight hours after their occurrence, and the Board were further empowered to direct returns to be made of all accidents, whether attended with personal injury or not. With a view to the public safety, disputes between railway companies having become common terns, or using a portion of the same line of track in common, were to be decided by the Board of Trade; and all powers, under existing acts, of making branch communications with railways, and of running locomotive engines upon them, were submitted to their regulations. They were also authorised to enforce the alteration of level crossings which appeared to endanger the public safety.

The same act required all railway companies to convey Baggage, Luggage, Messengers, and the Police at such rates, and upon such conditions as may be contracted for in the manner prescribed.

In the case of the railway where such a rate is fixed, the duty upon passengers conveyed by railway is chargeable at the rate of 5 per cent. 'Up on all sums received or charged for the hire, fare, or conveyance of such passengers.' The amount paid by the several companies from the 1st September, 1845, to 1st July, 1846, was £4,884 8s. 8d, and the amount not charged on account of this exception of third-class passengers, was £21 13s. 3d. in all, at such rate or at such rate as the Board may direct.

By an act of the 1 & 2 Vict. c. 98 provision had been made for securing advantageous arrangements upon railways for the conveyance of the mails, and by this act additional facilities were given for that purpose.

In regard to new railways also, a further provision was introduced in respect to the conveyance of troops, requiring every commissioned officer proceeding on duty to be conveyed in a first-class railway carriage, or at least in a second-class carriage. Every soldier or policeman, and their wives, widows, and children above twelve years of age, in a carriage provided with seats, and protected from the weather, at 1d. a mile.
children under three years being taken without charge, and
under twelve at half price, as in the case of the cheap trains.

The companies are required to convey military stores, baggage and arms, at 2d. a ton per mile, the assistance of the military in the settlement of which is necessary in case of an
arson, powder and other combustible matters at such prices and
under such conditions as may be contracted for with the secre-
tary general.

It was also enacted that every railway shall be bound to allow
a line of electric telegraph to be laid down for her major-
stasy's service upon lands adjoining the railway, and to give
every facility for conveying messages and telegrams. Such
powers were not otherwise than absolute, and the civil
powers upon the company and by the company upon share-
holders, and the recovery of damages and penalties. By a
similar act (c. 17), the sale of all lines of railroads was ex-
dated with respect to all companies incorporated for carrying
undertakings of a public nature in Scotland.

This is the 'Railways' Clauses Consolidation Act' (c. 18),
by which are amalgamated all previous enactments which
in acts authorizing the taking of lands for undertakings of a
public nature. It provides for the purchase of lands by agree-
ment, for the compulsory purchase of lands and the assessment
of their value, for the form of conveyances, the entry upon
the lands of the promoters of the undertaking, and for dealing
with the various interests in land, as copyholds, common lands,
mortgages, rent-charges, leases, &c. A similar act for the same
purposes was passed for Scotland (c. 19). These acts also
are applicable not only to railways but to all other un-
der takings in which compulsory powers of taking land are
necessary.

The last of the series is the 'Railways' Clauses Consolidation
Act' (c. 20), which consolidates all the usual provisions of
previous railway acts, which relate generally to the con-
struction of the line and the works connected with it, to the
operation of the line during the progress of the works, the con-
pensation of land during the process of the works, the crossing
of roads, the construction of bridges, and the works required
for the protection of the surrounding lands, and also regulations
which regulate the traffic in goods and passengers on the line,
and prescribes the use of suitable carriages and engines.

These acts did not affect the provisions of local acts which
had been passed before the session of 1845; but the acts of
that session and all subsequent acts have simply adopted the
three consolidation acts without repealing them, and where
any special powers not contained in these acts are sought for
by the parties, they are contained in distinct clauses, which are
obvious variations from the ordinary law.

In the same year it was observed that various railway acts of
that session had given to companies general powers of
granting or accepting leases, sales, or transfers, of their own
or other lines of railway; and as the exercise of such powers
without control was regarded as jealousy, as being liable to
lead to an amalgamation of lines, for which separate acts have
been passed, without the distinct authority of parliament be-
ing obtained, in each case; an Act (8 & 9 Vict., c. 96) was
designed, declaring that no such sale, lease, or transfer, should
be lawful, unless under the authority of a distinct provision in
some act of parliament, to the effect and purpose that the
railway to be leased, sold, or transferred, and the company or
party by whom such lease, &c., may be made, granted, or ac-
ceded.

Another act must here be referred to in connexion with
railways. The Joint Stock Companies' Act of 1844
(7 & 8 Vict., c. 110), though applying generally to
another class of companies with other objects, had a
bearing on the railway powers and duties, and was of
importance in connexion with railways. Before the passing of
this act, it was only necessary for railway companies to comply
with the standing orders of both Houses of Parliament before
they applied for a bill to authorise the undertaking; but other
conditions must now be complied with. Before the promoters
of a railway may publish any prospectus, handbill or advertise-
ment, they must return to the Registrar of Joint Stock
Companies, 1st, the proposed name of the company, 2nd, its
business or purpose; and 3rd, the names, occupations, &c., of
the promoters; and either before or after the prospectus is
published, they must return their provisional place of busi-
ness, the names of the committee, &c., with a written consent
of each promoter to become such, and an agreement to take
one or more shares; the names, residence, &c., of the officers
of the company, and of the subscribers; and a copy of the
prospectus itself before it is circulated. Where the company
the three first particulars, at least, are complied with, the
promoters are entitled to receive a certificate of provisional
registration.

The promoters may then assume the name of the proposed
company ' provisionally registered,' and may open subscrip-
tion lists, and allot shares and receive deposits not exceeding
eight years, for £100, and such further deposit as may be
required by the registrar, after which they may perform all the acts
necessary for obtaining an act of parliament.
In order to obtain a certificate of complete registration, the company must send to the registrar a copy of the Parliamentary Contract, and the 'Subscribers' Agreement, together with certificates of the deposit, at the proper offices, of the shares, bonds, debentures, and other securities. When the certificate has been obtained, the promoters may use the name of the company 'registered,' may have a common seal, may use and be used in their registered name, and may enter into contracts, conditionally upon the passing of the act, for the execution of works, for the supply of stores, or for any other necessary purpose of the company. Subject to these conditions the companies must comply with the standing orders of both the Houses of Parliament, and apply for bills to incorporate them and authorize their undertakings.

In the session of 1846 several acts were passed affecting railways. The first (9 & 10 Vict. c. 20) introduced and approved method of effecting the deposits of moneys required by the standing orders of Parliament, to be deposited by the subscribers to undertakings; and granting privileges, imposing Exchequer Bills and other public securities instead of money. This act was rendered necessary on account of the great inconvenience sustained by the promoters of railway bills and by the public, from large sums of money being suddenly withdrawn from the market which were locked up profitably in the hands of the accountant-general of the Court of Chancery, and were not very readily invested in government set series.

The second (9 & 10 Vict. c. 28) facilitated the dissolution of railway companies which had not on the 3rd of July, 1846, obtained acts of parliament to authorize their undertakings, and had the form and arrangements under which such dissolution should be effected.

The third is an act for constituting Commissioners of Railways, which transfers to the commissioners to be appointed all the powers and duties of the Railway Department of the Board of Trade. The commission is to consist of a president, with a salary of 2000l. a year, two paid commissioners, with salaries of 1500l. and two unpaid commissioners. The president is to be appointed by the Lord Chancellor, and the commissioners, all and by ballot in Parliament; but the two paid commissioners will be disqualified.

In addition to the ordinary power of the Railway Department they are to examine and report upon any subject relating to any railway or proposed railway, which shall be specially referred to them for their opinion, by Her Majesty or by either House of Parliament. And authority is given for, that purpose, to inspect and survey any proposed line of railway, with all the powers possessed by the officers engaged in the Ordnance Survey, and to charge the expenses to the promoters.

Though not directly applicable to railways, may here be cited. By one the ancient law of deodands was abolished (9 & 10 Vict. c. 63); and by the other a mode of recovering compensation where death is caused by accident. In such cases, compensation is to be brought by the executor or administrator of the deceased, for the benefit of the wife, husband, parent, and child; and the damages which may be recovered from the parties by the deceased, if an accident was caused, are to be divided amongst the several parties in such shares as the jury shall direct. (9 & 10 Vict. c. 53.)

This is assuredly a wise amendment of the law, as it substitutes a compensation to the relatives of the deceased for a deodand upon the engine or carriage, which is paid, as chance may determine, to the lord of the manor or to the crown.

These are the several statutes relating to railways; and a few results will be sufficient to explain their general operation and the proceedings which have been adopted for carrying into effect their provisions. It has already been stated that, by virtue of the act of 1844, the Railway Department of the Board of Trade was constituted. Its general object was to enforce the provisions of that and other acts, and to report to Parliament its own proceedings, the progress of railway communication, the accidents which occurred, and other matters which may arise. To this end, the members of the Department were originally confined therefore to the general supervision of railways already authorised by Parliament; and although railway bills were sent to the Board of Trade, it was not competent for the Department to take any active or ostensible part in reference to railway schemes about to be submitted to parliamentary investigation; but in consequence of the recommendations of a select committee of the House of Commons in 1846, the Board was instructed by the Lords of the Committee of Privy Council for Trade to undertake a preliminary examination of all railway schemes, to publish their decisions in the 'London Gazette,' and subsequently to submit detailed reports for the information of Parliament. This plan of investigating railway schemes out of Parliament, and submitted to Parliament, was adopted by Parliament merely as a means towards the formation of its own conclusions. It had been tried in the case of the four competing lines to Brighton in 1836; and in respect of the communication between London, Dublin, Edinburgh and Glasgow, and more extensively between London and the north of Ireland, in 1837; but this was the first experiment that had been made of a systematic investigation of all railway schemes by a government department, in anticipation of the introduction of any such schemes into Parliament. The Department had expressly declared that the reports of the railway department would in no sense be conclusive of the merits of the several schemes submitted to it, but that they would be regarded by parliament merely as aids towards the formation of its own conclusions (5th Report, p. xvi.): but the publication of its decisions in the Gazette, and the authoritative character of its opinions, and the reports produced a very general impression that it had been invested with much greater authority than it really possessed, and that its adjudications would be acknowledged by parliament as final. On the meeting of parliament, however, in 1846, this opinion was very soon discovered to be erroneous, and conclusions of the House of Commons proceeded with the investigation of the several bills very much in the same manner as if no reports had been made to Parliament.

In many cases their decisions may have been influenced by the reports of the Board of Trade, but the reports themselves, though ably written and often of the highest value, were not founded upon a public examination of the schemes, and a full hearing of the parties, and on that account did not obtain such confidence as to be held conclusive, when interests of such magnitude were concerned.

And it may be doubted whether, under any circumstances, any body whatever, less strong and irresponsible than parliament itself, could at that time have withstood the powerful influences of railway companies and speculators. At all events this experiment of the railway department was abandoned, and the Privy Council for Trade, of the 10th of July, 1845, the Board has since directed its attention to questions affecting the public safety and to considerations of public utility, but has in no case pronounced an opinion on the actual or comparative merits of any railway schemes. During the whole of the session of 1846 there was an unprecedented pressure of railway business before parliament, but without any aid from the government it was disposed of, in the usual manner, by committees.

It has been stated that all the powers of the Railway Department of the Board of Trade have been transferred, and that the board is no longer liable to the Commissioners of Railways; and it is most probable that the expense of regulating the merits of railway schemes, which failed before, may now be revived; but under the act it will be confined to such cases as have not been the subject of legislation, or in which the crown or any other House of Parliament, or the Privy Council for Trade, of the 10th of July, 1845, the Board has since directed its attention to questions affecting the public safety and to considerations of public utility, but has in no case pronounced an opinion on the actual or comparative merits of any railway schemes. allowing a nearer adherence to the nature, surface, leads to considerable saving of expense in comparatively easy countries, while it allows the conducting of railways in many cases through districts which, a few years since, would have been deemed utterly impracticable. The Lancaster and Carlisle and the Liverpool and Manchester Railway are instances of its success in the country where, notwithstanding the introduction of gigantic engineering works to improve the gradients, several long and steep slopes occur, are cases in point. On the Carlisle line especially very formidable slopes were found unavoidable, those between Beattock and the summit of the Clyde pass, a distance of nearly 14 miles, averaging 1 in 65, and containing an ascent of 1,000 ft. per mile. These having proved, in the view of the Great Eastern Railway, a branch of the South-Eastern Railway is another example, upon a smaller scale, in which experience has proved that with engines of suitable construction, a line with an average rise of 1 in 100 for upwards of 4 miles, part of which has a slope of 1 in 80, and which, owing to the peculiarly difficult nature of the country, forms a continuous series of curves of smaller radius than is usual upon locomotive lines, may be worked in both directions with speed, safety, and regularity. In the Report of the Railway Department of the Board of Trade in 1845 upon projected railways in the Manchester and Leeds districts many cases are cited in proof of the assertion that such roads as the everlasting inhabitant of the country might adopt every day as a matter of course; and as the capabilities of the locomotive have been enlarged, gradients of a class which would have been considered a few years ago altogether impracticable are now successfully negotiated. In all these cases cited are the inclined planes on the London and Birmingham Railway, from the Euston Square station to Camden Town, rising in some parts at the rates of 1 in 65 and 1 in 75; that by the Great Western Railway connecting Highnam to Gloucester, with the Victoria station at Manchester, rising 1 in 59 for 1000 yards and 1 in 49 for 640 yards; and that by which the Edinburgh and Glasgow Railway is connected into Glasgow with the Great Western Railway at 1 in 62 for 15 miles, in all of which the use of stationary engines and ropes had been either wholly or in a great measure discontinued, it being found that the trains might be worked more efficiently and more conveniently by locomotive engines. The Lickey incline, on the Birmingham and Gloucester Railway, is likewise referred to as a conclusive proof that a gradient of 1 in 574 for a length of 2 miles 3 chains may be worked by the aid of an engine constructed for the purpose, without serious inconvenience to an extensive traffic; and as a proof that such an incline may be descended without danger by the force of gravity, regulated by the action of brakes. In reference to curves it is observed in the same Report that practical experience has led to a similar modification of the views formerly entertained. 'The Newcastle and Carlisle Railway,' observes the Report, 'presents cases where the plans and sections of the inclines, the ascent and descent of curves, of every degree of curvature, up to 8 chains radius, and with steep inclines, being worked with economy and safety; and, among other cases, there are upon the Manchester, Leeds, and Carlisle Railway, one (Plan 2) of (plains yards) radius, away from any station, and in a gradient of 1 in 82, over which their trains have been worked for upwards of four years, without the slightest accident or practical inconvenience.' Special precautions are, however, adopted to prevent danger; the engine-drivers being warned by inscribed boards at the side of the railway to shut off their steam on approaching the curves referred to.

As connected with the design of a line of railway we may further observe, that surface-crossings have been allowed much more extensively in recent railway acts than in those of 1825 and 1830, because there was a great saving of line by using one. After the great period of railway speculation in 1830 and 1837 the degree of uncertainty which yet remained respecting the remunerative character of railways, combined with the enormous excess in the cost of most of the lines in progress above the parliamentary estimates, and with some other circumstances, almost put a stop to the commencement of any new schemes; and when at length, in the sessions of 1842 and 1843, symptoms of revival began to appear, the new schemes brought forward were mostly under a guarantee from some established company, and were, almost without exception, distinguished by features calculated to reduce the cost of construction, in every instance except that of the adhesion of the earth-works by the adoption, as above explained, of comparatively steep gradients. This peculiarity, by keeping the level of the railway nearer to the natural surface of the ground, led necessarily to the more frequent use of surface-crossings; because the economy of construction aimed at would have been neutralised if, as most often has happened in a level country, the roads crossing the railway had to be raised or lowered, and passed by means of bridges. These principles of cheap construction were very closely canvassed and decided on at the Old Court, on thexee of the London and Birmingham branch. The Northampton and Peterborough branch from the London and Birmingham railway; and having been sanctioned by parliament in that case, were soon applied to several other lines, for which acts were obtained in 1844 and 1845. Most of the lines thus projected for working with a single track either have been or are likely to be doubled, the increase of traffic and the necessity of having a single track for such a measure necessary; but their other peculiarities remained, as, and have been largely imitated in the new lines sanctioned in 1846, upon which surface-crossings are very numerous. Wherever this mode of crossing is allowed, the gates are kept shut across the road, excepting when opened by an attendant, so that the danger occasioned to trains upon the railway is exceedingly slight.

**Permanent Way.**—In the construction of the upper works of a railway, to which this name is given, more extended experience appears to be leading engineers to a greater uniformity of practice than prevailed when the F. C. article, which the present writer had the pleasure of contributing last year, was written. The principle of affording continuous support to the rails by means of longitudinal timber bearings, although still adhered to by Mr. Brunel, and employed upon lines in connexion with the Great Western and Great Eastern railways, is now followed by the majority of other engineers; it being found that their use involves some loss of engine-power, probably from the greater yielding of the road, occasioned or favoured by the actual lightness of the rails as compared with those of the earlier systems, and also by the action of the treads and by the comparative weakness of their form. This peculiarity has been ingeniously turned to advantage by Mr. Brunel in the descending track in the Box tunnel, upon the Great Western Railway, for the proposed additional line between Wiveliscombe and the West Country, where it is stated in the Parliamentary evidence that the line is particularly subject to the action of rain, the hill being covered with thick grass; that by installing the railway in the Box tunnel, upon the Great Western Railway, for the proposed additional line between Wiveliscombe and the West Country, where it is stated in the Parliamentary evidence that the line is particularly subject to the action of rain, the hill being covered with thick grass; there is a decided preference for the cross-sleepers, which, it is observed, in the case of many railways, the incline, the treads, and the comparative weakness of their form. On the Hull and Selby (narrow gauge) line, which was partly laid upon longitudinal timbers and partly upon transverse wooden sleepers, a good opportunity was afforded for comparing the two classes. In the Bearhull tunnel, Mr. Gray, who was formerly locomotive superintendent upon that line, shows a decided preference for the cross-sleepers. He observes that there was a great difficulty in keeping the rail in perfect contact with the longitudinal timbers; that they require to be pressed upon the timber with a constant pressure nearly equal to that coming upon them during the passage of a train; and that in the absence of such a pressure, which is unattainable by any mode of fastening now in use, water gets in between the rail and the timber in wet weather, and is forced out with great violence during the passage of an engine; each wheel carrying it out against the timber; 'I have,' says Mr. Gray, 'seen the engine going out almost as clean as a new pin, and before half an hour had elapsed you could scarcely see a clean spot on it.' He further states that, having been told by an engine-driver that his wheels were slipped more upon the longitudinal timbers than upon the cross-sleepers, he, though incredulous, tried it himself one frosty morning, and found that after the engine slipping so much upon a level part of the road which was laid upon longitudinal timbers as to lead him to fear that the train would be unable to ascend an incline of 16 feet per mile which it was approaching, he found, on reaching the incline, which was laid with cross-sleepers, that the train 'went up like an arrow.' The slipping re-commenced on reaching another portion of road laid on longitudinal timbers, and again stopped on reaching the cross-sleepers. Upon the Croydon railway, which was originally laid with longitudi-
fusal timbers, the construction has been found so unsatisfactory that, in the •writing, it is nearly impossible at the time we write (November 1846), heavy bridge rails, laid upon cross-sleepers, have been employed.

The kind of rail now most commonly employed resembles the one described in the first inserted extract of the article on RAILWAY, P. C., which is variously called the I, the II, and the double-T-rail; and the weight is seldom less than 75 or 76 lbs. per yard. In some cases heavier rails have been used; the heaviest yet employed, we believe, being those laid on the Great Southern and Western (of Ireland) Railway, between Dublin and Carlow, by Sir John Macnelli, which weigh 90 lbs. per yard. These rails however are laid in a peculiar arrangement, and are not the subject of the present notice, of which the natural tendency is to attract the material to decay. The permanent way of the South Eastern Railway, laid under the superintendence of Mr. Wiliam Cubitt, is an excellent example of the cross-sleeper construction, which has been adopted on the Continent and in several other railways. A minute account of this permanent way, communicated by Mr. Pope to the Institution of Civil Engineers, was printed in the Civil Engineer's and Architect's Journal, for June, 1842, pp. 299-302, which, as well as a shorter notice in the Railway Chronicle for 1846, p. 209, is illustrated by engravings of the mechanical details. The rails, which are washed of a regular triangular section, 9 feet long, 11½ inches broad, and 7 inches deep, formed by sawing square baulks of Baltic fir diagonally into four pieces. These are laid with the broadest flat surface (the base of the triangle) uppermost, the double slope of the under side constituting a form admirably adapted for bedding itself well in the ballast. The chairs, which are of a pattern patented by Messrs. Ramsone and Macnelli, are of a shape yet to be seen in this country, and are devised to keep the track in the straightest line and to ensure the greatest strength from a given weight of iron, and have a single projecting rib or buttress in the centre of each chair, which is cast and left in the case of the original of sufficient size to secure the sleeper by two pins, one at each end, the holes to receive them being formed alternately on opposite sides of the medial line of the chair and sleeper, that the driving of the pins may have the least possible tendency to split the sleeper. The joint-chairs however, or those which are used at the junction of two lengths of rail, have three instead of two holes to receive the fastening pins, which are trentls of compressed oak, 6 inches long, and tapering from 1½ inch to 1 inch in diameter. The cavity in the chair is so contrived that the rail shall only touch it at two points, the base and the top of the chair, and so arranged that the true centre of the sleeper of the rail, and its steadiness in the chair, may not be affected by any trifling irregularity of shape; and the rails are secured in their place by keys of compressed oak. Upon the South Eastern line the rails weigh 76 lbs. per yard, the ordinary chairs 20 lbs. each, and the joint-chairs 28 lbs.; and the chairs and sleepers are placed at an average distance of 3 feet from each other. The first freight train, in each section, is placed at a distance of 2 feet 6 inches to 2 feet 8 inches, while the intermediate space is divided into three equal parts. Upon the Croydon line rails weigh 75 lbs. to the yard, and the ordinary chairs 20 lbs., joint-chairs 30 lbs., and six, instead of five, sleepers to the 16-feet rail.

A communication made by Mr. W. H. Barlow to the Institution of Civil Engineers on the 14th of January, 1845, and printed in the Appendix to the Institution for that year, p. 24, treats of the kind of hollow or tubular key of wrought-iron, made to press equally against the jaw of the chair, the middle web of the rail, and disposed at both ends, for the purpose of substituting for the compressed wooden keys so generally used; which, from their position just above the surface of the ground, are much exposed to decay, and are also liable to be injured by the driving of the sleepers to their settle by the chink or smite. On the Midland Counties Railway the wooden keys have not been found to last more than about five years; and as they cost from 8d. to 10d. per 1000 (upwards of 7000 being employed in a mile of railway with double twelve, or 3 feet apart), the expense of renewal becomes an important item.

In addition to the evidence before the Gauge Commissioners, already referred to, which is well worthy of diligent perusal for its information upon this and other branches of railway engineering, the reader may consult with advantage the reports given in the 'Civil Engineer's and Architect's Journal,' of Mr. Vignoles's lectures, delivered when professor of civil engineering at University College, London, and which, reported in the number for September, 1845, pp. 319, 313, relate solely to the permanent way, or upper works of railways.

Gauge.—It has been stated under RAILWAY, p. 256, that the gauge, or width of track, upon the Liverpool and Manchester railway, which subsequently became the model for other lines, was copied from some of the colliery railways in the North of England, and this arrangement has been found amply sufficient for mineral traffic, allowing as it does, by the projection of the body over the wheels, the use of carriages to the full as large as any employed upon common roads. The gauge was laid down before it was determined by what power to work it, so that, although practical experience might have been cited in proof of the sufficiency of a smaller gauge for the use of locomotive engines, the gauge appears to have been adopted for the sake of convenience, without reference to the motive power. Soon however, after the successful application of locomotive engines to the attainment of a high rate of speed, the gauge thus insufficient for locomotive engines, the gauge was considered as too small to allow of the safety of running them under the weight of a train, and the whole matter was referred to the Railway Commission, for consideration.

It became a favourite idea with many engineer-builders, that a few additional inches to the gauge would increase the power, and in every way much improve the locomotive; while others, considering that all railways must eventually communicate, applied themselves to simplify the engine and adapting it to the gauge; and, he adds, 'even up to the present day, the question is, shall the engine be adapted to the gauge, or the gauge to the engine?'

The railways which were projected in immediate connection with the Liverpool and Manchester adopted its gauge, as may be first contemplated for the Great Western Railway, which, as originally projected, was to commence by a junction with the London and Birmingham line a few miles from London. As, however, it ran into an entirely new district of country, and one in which the lines of a very superior order were attainable, it was determined, upon the recommendation of Mr. Brunel, to seek for an independent entrance into London, and, by the adoption of a wider gauge, to aim at a higher degree of speed, and a higher accommodation than any other line could afford. It was then believed that each main-trunk railway would continue in a great measure independent of each other, and therefore that no serious difficulties would arise from the diversity of gauge, and Mr. Brunel conceived that by the adoption of a gauge of 7 feet instead of that of 4 feet 8½ inches, he should be able, by increasing the bodies of the carriages between instead of over the wheels (a construction, we may observe, which he has not tried, and against which several important reasons might be urged), to save friction by the employment of larger wheels, which, without this, would be of a gravity higher than in ordinary railway carriages; that he should thus also ensure greater stability and a more steady motion; that he should be able to convey more passengers and other common road carriages than could be by any other means; that he should obtain facilities for the adoption of larger and more powerful engines than had as yet been used upon any railway; and thus, by a combination of mechanical facilities, he was able to make the advantage of the superior levels of the line for the attainment of very high speed.
progress of the works some of the shareholders became dissatisfied with the increased expenditure involved in the adoption of this greatly enlarged gauge, and at length, in 1858, Mr. John Corbet, the Great Western's experienced engineer, was called in to examine and report upon the works of the Great Western line, which was then completed as far as Maidenhead, especially in reference to the increased gauge. The result was that the broad-gauge, as it was called in the narrow-gauge, did not lead to any change in this particular, and consequently the construction of the Great Western line, with its extension to Exeter, and its first important branch, the Great Western and Northern Counties limited line, was carried forward upon the 7 feet gauge. In the mean time the Eastern Counties railway, another line which was then expected to continue in a great measure isolated, was, upon the recommendation of the Board of Trade, in 1859, examined and reported upon by an expert committee appointed for the purpose, and the conclusion arrived at was that the 7 feet gauge was equal to the 10 feet or broad-gauge, and the question of the 7 feet gauge was consequently abandoned. The immediate result of this was the great advantage which the 7 feet gauge was to the London and South Western Railway, which at that time was on the 7 feet gauge. That line, in consequence, was able to carry by a large margin the traffic which the Great Western had sought to divert to its broad-gauge line, and, of course, was able to realize a commercial success which, had the Great Western been allowed to carry on its way, would have been equal to that of the South Western Railway, from the fact that the profit of the Great Western was equal to, and at that time exceeded, that of the South Western. The result was, however, that the Great Western lost a large part of its traffic, and was, throughout the remainder of its career, discontented with the decision of the Board of Trade; and, in this connection, it is interesting to note that the Court of Arbitration, in awarding the Great Western the damages which it claimed in reference to this decision, decided in favour of the Great Western Railway Company, and awarded it damages of £30,000, in addition to the costs of the action. This decision was, however, reversed by the Court of Appeal, and the damages awarded to the Great Western were reduced to £10,000.

In the parliamentary session of 1845 the gauge question assumed great prominence in consequence of the obstinate contest then carried on between the broad and narrow gauge interests for the privilege of constructing lines between Oxford, to which place the Great Western company had a broad-gauge branch formed under an act of 1843, and Rugby on the one hand, and between Oxford and Birmingham on the other, which was then under construction. The Board of Trade reported against the broad-gauge lines mainly upon the ground that an extension of the broad gauge into a new district of such importance was objectionable, both from the point of view of the traffic, a much larger number of the stock would be required, and the belief that the broad gauge would be more injurious if carried into the interior of the commercial district than if limited to the port of Bristol (it being then proposed to reduce the Bristol and Gloucester line to the narrow gauge), and the junction at Oxford. Parliament, however, finally determined in favour of the lines promoted by the Great Western company, chiefly upon the ground of their engineering superiority, but without expressing any decided opinion upon the question of gauge, which had, by this memorable contest, assumed a national importance. Indirectly it led to a full investigation of the question in the House of Commons, and an address being, before the close of the session, presented to the House of Lords on the motion of Lord Dalhousie, and in the House of Commons by the motion of Mr. Cobden, for a royal commission to inquire and report whether in future private acts for the construction of railways ought to be made for securing a uniform gauge; and whether it would be expedient and practicable to take measures to bring railways already constructed, or in progress of construction, into uniform gauge. The commissioners appointed in consequence of this motion were Colonel Sir Frederic Smith, of the Royal Engineers, who had for some years been connected with the Office of Inspector-General of Railways under the Board of Trade; Mr. Pollock, of the Worcestershire Military Academy, who had some years before been upon the Irish Railway Commission; and Professor Airy, the Astronomer-Royal. After a careful investigation, in the course of which many experts examined, experiments were tried upon both gauges, and important statistical returns were obtained from the various railway companies, these gentlemen, in January, 1846, made a report in which they unreservedly pronounced in favour of the 7 feet gauge, on the ground that, in fast or express trains than by any others, much persons being seldom encumbered with much luggage, and no carriages or horses being, under ordinary circumstances, conveyed by such trains. But with respect to local traffic or for comparatively trifling distance, confusion, and personal discomfort, with some risk of loss of luggage during the transfer. In the case of ordinary or mixed trains, which convey many more passengers, and a much larger quantity of luggage, the evils would be much more serious. Experience shows how greatly those trains are preferred in which, although the traveller may have to pass over the lines of different companies, passengers may be conveyed from end to end of the journey without change of carriage; and many companies meet this preference, and the desire to have luggage undisturbed, by an arrangement of the line, bringing them hack empty. The transfer of carriages and horses involves also much delay, and in the case of many horses, danger also. With reference to such trains the commissioners observe that 'the change of one line of road for another, in the transference of luggage of an entire train of much extent, must even in the day-time be an inconvenience of a very serious nature; but at night it would be an intolerable evil: and we think legislative interference is called for to remove or mitigate such an evil.' With reference to goods trains also, the evidence of carriers was very decisive as to the evils attending any such disturbance and re-arranging as must take place on such a set of trains. And, in such an event, the evidence shows that the inconvenience, if any, was trifling, and the working of the lines of one company running upon the same line, would be little disturbed, and the carrying of goods by passenger trains was found to be far more formidable.

In the parliamentary session of 1845 the gauge question assumed great prominence in consequence of the obstinate contest then carried on between the broad and narrow gauge interests for the privilege of constructing lines between Oxford, to which place the Great Western company had a broad-gauge branch formed under an act of 1843, and Rugby on the one hand, and between Oxford and Birmingham on the other, which was then under construction. The Board of Trade reported against the broad-gauge lines mainly upon the ground that an extension of the broad gauge into a new district of such importance was objectionable, both from the point of view of the traffic, a much larger number of the stock would be required, and the belief that the broad gauge would be more injurious if carried into the interior of the commercial district than if limited to the port of Bristol (it being then proposed to reduce the Bristol and Gloucester line to the narrow gauge), and the junction at Oxford. Parliament, however, finally determined in favour of the lines promoted by the Great Western company, chiefly upon the ground of their engineering superiority, but without expressing any decided opinion upon the question of gauge, which had, by this memorable contest, assumed a national importance. Indirectly it led to a full investigation of the question in the House of Commons, and an address being, before the close of the session, presented to the House of Lords on the motion of Lord Dalhousie, and in the House of Commons by the motion of Mr. Cobden, for a royal commission to inquire and report whether in future private acts for the construction of railways ought to be made for securing a uniform gauge; and whether it would be expedient and practicable to take measures to bring railways already constructed, or in progress of construction, into uniform gauge. With reference to goods trains also, the evidence of carriers was very decisive as to the evils attending any such disturbance and re-arranging as must take place on such a set of trains. And, in such an event, the evidence shows that the inconvenience, if any, was trifling, and the working of the lines of one company running upon the same line, would be little disturbed, and the carrying of goods by passenger trains was found to be far more formidable.
sum up their conclusions upon this head by stating their belief that no method had been proposed to them 'which is calculated to remedy in any important degree the inconvenience attending a break of gauge.'

In reference to the policy of establishing uniformity of gauge it is interesting to examine briefly the opinion of ordinary and professional men as to the conviction that the time has arrived when, if steps cannot be taken to remove the existing evil of diversity, it appears at least imperative that the wider spread of the evil should be prevented. In the question proposed the existing state of things in this country, involves, they observe, not only the consideration of the relative length of the lines laid on the two different systems which now remain, England, 'the nation of four gauges,' and for that reason the greater superiority of one over the other, their adaptation to the wants of the country, and the possibility as well as the policy of a change, but also the pecuniary means of effecting it.' Another view of the subject relates to the expediency of laying additional rails to enable carriages suitable for both gauges to run upon the same line, a plan attended with several difficulties, but which is expected to be adopted in some places where, under present arrangements, the two gauges will intermingle. The difficulty of keeping such a double-gauge road in repair would be serious, and the complication introduced at points and stations would be very likely to affect the speed and safety. If this were done in the cheapest way, by the addition of a third rail only, carriages of both gauges could not be safely used in one train, because the centre of traction would not be the same, while if two additional rails were used the expense would be great, and the complication would be still further increased. This point was illustrated in the evidence of Mr. Wyndham Harding, who showed by a diagram that while at a junction between a broad-gauge and a narrow-gauge line, with two trains running, if between the two running stations, there are only six crossings or intersections of the rails, the number is increased by the addition of two supplementary rails to each track, to twenty-eight. It was further pointed out that in the event of any accident or obstruction to traffic, the attendants of the carriages of different widths on the same line from the circumstance that the station-platforms made to suit the broad would be too far off from the narrow carriages.

After the question, so far as regards the question of the accommodation of a comparatively small number of persons, however desirable that may be to them, of as far less moment than that of affording increased convenience to the general commercial traffic,' they considered the narrow gauge preferable for public convenience, and, were it imperative to produce uniformity, would recommend the alteration of the broad to the narrow gauge; especially taking into consideration 'that the extent of the former at present in works is only 274 miles, while that of the latter is not less than 1901 miles,' and that the alteration of such lines would require the expenditure of much money. The objection of theRICS that accidents which cause such evils were more likely to occur on the greater trunk-lines ' of railway, such as are now in practical operation, 'a superiority were due to the broad-gauge system, that superiority would be less for lines yet to be constructed: a small improvement in the present lines, and any consideration of preferrence were given to the narrow gauge for the existing lines, that system would be still more entitled to the preference for the railways of smaller traffic to which we look forward.'

After stating that 'the evils which have been generally attributed to the narrow gauge, with well-proportioned engines for traffic, and yet in general these are judged commercially to be less costly, as well as the less difficult operation.' The question of an intermediate gauge is treated very briefly by the Committee of Inquiry. There is evidence obtained to the efficiency of the 4 feet 8½ inches gauge upon both English and Continental railways, was such as to counterbalance any theoretical advantage to be derived from a costly alteration to a gauge of 6 feet, 5 feet 6 inches (which, upon the recommendation of the Board of Trade, had been previously determined as the national or standard gauge for Irish railways, 6 feet 6 inches, or 6 feet, which latter is the largest dimension now adopted by any not directly interested in the 7-feet gauge. They computed that the total expense of altering the then existing broad-gauge lines to the narrow gauge, including the alteration or substitution of locomotives and carrying stock, would be enormous, and that they could not recommend any such alteration at the public expense, nor conceive that the broad-gauge companies could be fairly required to make it at their own cost, they do recommend that the scheme of 4 feet 8½ inches, which has been adopted by the legislature to be the gauge to be used in all public railways now under construction, or hereafter to be constructed, in Great Britain; that no subsequent alteration of such gauge would be necessary to the present line, the question of the speed of railroads for the general public, and the measures be taken to complete the general chain of narrow-gauge communication from the north of England to the southern coast; and that to avoid the evils of breaking gauges at the junctions, the gauges of the various lines can be taken along sharper curves than would be suited to a broader wagon; and are therefore more suitable where, as is often the case in such districts, the broken nature of the ground renders
on the narrow gauge, with the existing broad-gauge railways, some equitable means should be found of either producing entire uniformity by the reduction of existing lines, or of adopting such measures as shall admit of the narrow-gauge carriages passing without interruption or damage along them.

The appearance of this report was speedily followed by the publication of a pamphlet in support of the motion of the members of the broad-gauge party as a kind of counter report; would, if adopted, 'inevitably terminate all chance of future improvements in railway travelling,' by arresting the progress of that comparatively new department. Nevertheless, the report of the broad-gauge party, and to those who had made the most strenuous efforts on the part of those interested in the broad gauge, to reverse or modify the recommendations of the commissioners, which, it was contended, Observations on the result of the inquiry of the commissioners of 1846, for the accommodation of all the persons, and at a late period of the session of 1846 a bill was introduced, which subsequently became law, founded upon their suggestions. Admitting the general conclusions of the commissioners, the Board appears to have entertained the stamp of uniformity impracticable; and the act for the regulation of gauge therefore simply provides for uniformity upon such new lines as are not directly connected with the existing broad gauge, from cities, towns, or places of in the year 1846, to Rugby and Wrexham, and into South Wales; and also in the country lying to the south and west of the Great Western and Bristol and Exeter lines, connected by the use of extensions of a few miles in length from the Great Western railway, and to such other cases as may be specially sanctioned by parliament. Under the operation of this act, the Birmingham and Oxford Junction line, although projected as an extension of the broad-gauge system, must be laid upon the narrow gauge, unless, as its promoters anticipate, powers for adopting the wide gauge may be obtained in a future session.

It is felt by many who have deeply studied the subject, that this compromising arrangement must be regarded merely as a temporary adjustment of the difficulty, and that increased experience will convince even the proponents of the broad-gauge lines of the necessity, for the promotion of their own interests as well as of the convenience of the public, of reducing their gauge to the national standard.

This important subject has already occupied so much of our space, that our remarks, founded upon the instructive evidence which has been brought before the public by the recent investigation, must be limited to two leading points, in both of which the public are deeply interested. The first of these is the relative proportion and contemplated ultimate breadth of the railroads which have already happened which can be regarded as even remotely bearing on the question of gauge, is too small to enable us to find any general conclusions upon them. Provisions have been made for the construction of narrow-gauge lines, where due care is exercised, is almost as great as can be expected. The comparative narrowness of base, which, as far as we remember, is the only definite element of danger charged upon the broad-gauge lines, of the necessity for the provision of their own interests as well as of the convenience of the public, of reducing their gauge to the national standard.

The second point is which we would direct attention is the bearing of the gauge question upon the future prospects of the railway system, not as regards the importance of uniformity, or the comparative cost of construction and working; which points have been fully considered by the commissioners, but in reference to another feature involving the comparative merits of the gauges themselves. Admitting, for the sake of argument, that the broad gauge does offer greater facilities for conducting a very extensive traffic, which may be advantageously concentrated into heavy trains, it is well to bear in mind that the tendency of the numerous competing lines now in progress for the accommodation of heavy traffic, by the use of extensive trunk lines, is to promote and render necessary the subdivision of traffic into small rather than its concentration into large trains, in order that the local traffic of such numerous lines may be employed to the utmost, to the injury of the passenger or freight traffic, and by the lighter trains calling at numerous minor stations. All these considerations point towards the peculiar facilities of a narrow gauge as prospectively more desirable than the power of moving large numbers of passengers or goods has been proved injurious in an important degree. Probably no accident has ever occurred of which it can be regarded as the cause, and we are not aware of any in which it can be proved to have increased the damage. On the other hand, while it might be difficult to say that any particular accident which has happened upon a broad-gauge line might not have occurred had the gauge been narrower, the increased width in may in many cases be seen to be an injurious effect.

The greater weight of the engine and the larger amount of dead weight which, in practice, attends the use of broad-gauge carriages, increase the injurious effects of that almost irresistible motion. While it is easy to point to lines, and within which gives so fearful a character to many railway accidents. The greater length of the axle, although accompanied by increased tendency, increases the probability of fracture, or of such straining the rails, and the wheels, as which give the view, and under ordinary circumstances, this evil is aggravated by the use of large wheels, which, when their flanges come in contact with the rails, act upon the axles with greater leverage than small. It is well known that the curve of given radius is less easily rounded by a broad than by a narrow-gauge carriage, and that the rails are more likely to be damaged by a heavy than by a light engine, we cannot avoid the conclusion that the large and heavy engines with advantage. With regard to the line by the failure of axles are considerably augmented by
ero company, its uniformity appears even more striking.

The mines and iron-works in that district are usually situated in narrow valleys or gullies, in which sharp curves are unavoidable; and, to suit the peculiarities of the country, the local tramways are usually narrower than the common narrow gauge, and some of them as narrow as 2 feet 6 inches.

Allusion was made in the course of the gauge evidence to the practice of sending passengers through from end to end of their journey without change of carriage, although they might have to pass over the lines of different companies. Those witnesses who endeavoured to mitigate the evils of variety of gauge pleaded, that as branches and connecting lines multiply, the advantages of running a line in which continuous running by a single way extended, without being required to change their carriage; and that a similar principle must pervade the arrangements for working every description of through-traffic if the public is to be conciliated, and the usefulness of the railway system developed to its full extent. The importance and at the same time the difficulty of carrying out these principles became still more obvious when the lines extending from Rugby and Hampton to York were completed. For some time, however, discussions arose between the different companies; it was difficult to obtain accurate returns of, and payment for, the use made by the several companies of one another's carrying arrangements; and in a proper way, it is supposed by those companies, and are wagon-loads to an extent which amounted to a positive grievance. Under these circumstances it occurred both to Mr. Robert Stephenson and to Mr. K. Morrison, the present manager of the Railway Clearing-house, that a remedy might be found in the establishment of a central office on the principles of the Clearing-house by which the business of the London bankers is so materially facilitated. [BARK, P.C., p. 365.]

After some difficulties the proposed system was, on the 2nd of January, 1842, brought into operation on the railways extending from London to Darlington in one direction, and from Manchester to Hull in another. It has been since adopted by the companies whose lines extend from Darlington to Carlisle, Sunderland, Hartlepool, and Scarborough; and from Manchester to Liverpool, Fleetwood, Lancaster, and Manchester.

'In a few months,' according to the pamphlet above quoted, which does not allude to the probable further extension of the north of Scot-

land, and to other objects, and it grants leave to any line to be extended, it will be in force on all the railways included in the area defined by a line passing from London through Glasgow, Liverpool, Fleetwood, and Glasgow, to Edinburgh, and returning by Berwick, Newcastle, Scarborough, Hull, Yarmouth, and Cambridge, to the metropolis; or, in other words, on all the narrow-gauge railways in Great Britain lying north of the Thames, with the exception of the few short lines that are beyond the limit described; an area which, it is hardly necessary to observe, is only prevented from extending to the southern parts of England by the intervention of a different gauge.

One of the principles of the Clearing-house system, the regulations founded upon which are very rarely departed from, is, that passengers shall be booked through at all principal stations, and conveyed to their destination without change of carriage; that the journey be in one way carried through without change of conveyance, and goods without being shifted or re-assorted; that the company shall pay a fixed rate per mile for such carriages and wagons, not their own property, as they may need; and, a further sum per day by way of line or demurrage for detention, if kept beyond a prescribed length of time; and that all carriages be booked between the several companies shall pass through the Clearing-house. Without entering into the details of the method by which these objects are attained, or the advantages which either have been or are expected to be derived from the establishment of this system, the ultimate result of which will be to give to all the connected railways of Great Britain, as far as each is connected with the through-traffic, the character of one concern, conducted on a uniform system, we may state that the tables appended to the pamphlet show that in the year 1845, 517,886 passengers were conveyed in average distance of 144 miles, while the average length of the railways upon which the system is in operation being only 41 miles, each travelled on an average over nearly four different railways, and passed three junctions, without any notice of necessity, and at the same time these passengers, 59,765 railway carriages and 5813 trucks with private carriages were sent through. The tables further show that the endorsement of goods for the conveyance of coke, coal, and other minerals, of which no record is kept at the Clearing-house, 180,606 wagon-loads with merchandise were sent through in a similar manner.

Junctions, Station Conveniences, and Signals. Many ingenious contrivances of the switch kind are in use, which may appear to render accidents almost impossible, so far as the action of the moveable rails is concerned; but one of the most important precautions attending their use is that no generally adhered to, of making all sidings and crossings join the main line in such a way that trains must proceed backwards in order to enter, which is directly contrary to the spirit of the article RAILWAY, P. C., and reversing the position of the axes in the crossing marked 'f,' the reasons for this precaution will be readily understood. As the diagram now stands, the train running from e to f, and the lower to traffic running from f to e, it will be seen that (assuming the switches to be, as they usually are in such situations, of a self-acting kind, on the principle of that represented in Fig. 73) Put them in the other way, and being turned into the wrong line, the flanges of the train would open the switch, and it would continue its journey without danger. In order to enter a siding or crossing so laid, the train must run on past the switches, must then be brought to a stand, and be propelled backwards, by reversing the motion of the engine, when the switches are properly ad-
justed; but the trifling inconvenience and delay occasioned by this manoeuvre is vastly compensated by the greater security afforded by the arrangement to the transit of the ordinary trains, and all such as may have to pass the junction at considerable speed. The last few months have produced two or three other arrangements to reverse the rolling of carriages into the main line so as to meet the traffic, upon the Brightow, Lewes, and Hastings railway, where, as there was at first a chance of injury by the wheels of the train treading on the running line, such an arrangement was of course inevitable; while the increasing use of fast or express trains renders it highly important to adopt every precaution which may lessen the risk of running at full speed through stations where the use of switches and sidings is necessary. Accidents have occurred through the rolling of carriages from a siding on to the main line by the action of wind, or from some other cause, and thereby ex-
posing passing trains to danger; to guard against which self-acting clocks have been introduced in some situations. These consist of pieces of bent rail or other iron bar so mounted that, while they may be turned aside out of the way by the wheels of a train, whenever they are brought into position they rise up as soon as the carriage has passed, and prevent it from rolling back towards the main line, excepting while they are held back or clear of the rails by an attendant, by means of a lever handle similar to those used for working switches.

Another contrivance, which is sometimes adopted with similar intention to the above, affords the power of laying such tracks as are often required at stations to cross the main line for the express of a train, and to run to another, without in any way interfering with the rails of the main line. It consists in laying the rails which constitute the cross track about an inch above the level of the main line, cutting the wheels of the train, when they are in the crossing section. By this arrangement the flanges of a carriage being pushed across the cross track, mount upon and roll over the rails of the main line, supporting the weight of the carriage until the wheels again meet the elevated rails of the cross
The necessity for breaking the continuity of the main rails by the interposition of turn-tables, tended to dim the attractiveness of the improved apparatus, and the smoothness of the transit upon the main line is undisturbed.

Some important improvements in turn-tables, tending to diminish the noise occasioned by passing over them, deserve a passing notice. Some are laid with elevated cross tracks of the kind just described, so as to leave the rails of one track smooth and unbroken; and others are distinguished by contrivances to ensure firmness and stability during the passage of trains over them. Dunn's patent turn-table, the details of which are illustrated in the 'Railway Chronicle' for 1846, p. 347, provides for this purpose in such a manner as to make the table being accidentally left in a wrong position, in this contrivance the central portion of the tracks, both of the main and cross lines, is fixed or stationary, the only portion that actually turns being an annular platform, the surface of which is so adjusted to the level of the rails, that a carriage coming upon it when turned into a wrong position would roll over it upon its flanges, coming upon the fixed track in the centre soon enough to avoid any risk of being turned out of its proper course, and, crossing the second half of the annulus again upon its flanges, would reach the fixed track beyond it without being thrown off the line. Some ingenious features of this turn-table, besides the plan of its construction, which from this character we shall only advert to the admirable system of signals on the semaphore principle, introduced by Mr. C. H. Gregory upon the London and Croydon railway, and which, with various improvements suggested by experience, have been adopted on the lines of the South-Eastern, Brighton, and some other railway companies. The ordinary apparatus mounted at every station, and at each approach to stations of the more important class, consists of a semaphore pillar, near the main lines, of the arms mounted upon a common pivot near its upper extremity, either of which is capable of being moved independently of the other by means of a handle near the bottom of the post, so as either to hang vertically, in which position it falls into a slit in the post so as to be invisible; to project from it in a horizontal direction, or at an angle of 90°; or to assume a position intermediate between the vertical and the horizontal, projecting downwards at an angle of 45°. Each arm, whatever be its position, refers to its own particular point, that projecting towards the right referring to the right-hand track, and that projecting towards the left to the left-hand track, and when dropped within each other, so that the line to which it refers is clear, so that trains may pass safely; when projected horizontally, that a train is a short distance ahead, that there is some obstruction on the line, or that the station is occupied. In other words, when the pillar is or when projected at an angle of 45° that, owing to a train being ahead, though at a safe distance, or owing to some circumstance, any approaching train should slacken its speed, and any other signal, to be described hereafter, may also be employed.

The day-time, signal lamps, with powerful parabolic reflectors, and capable, by the turning of handles at the bottom of each post, of being shifted so as to throw their light through either a white or coloured, a red, or a green glass, according to whether the signal required be to indicate safety, danger, or the necessity of caution, are also mounted near the top of each post; one lamp directing its light up, and the other down the railway, and each being visible only in its own proper direction, for the guidance of approaching trains. At the junctions of two lines similar signals are used, but two posts are employed, one for each line, each having two arms, one for the down and the other for the up track of its particular line. The arms and lamps in this case have but two positions, on or off; the signal, which is always displayed excepting while the train is on its post and actually holding the switches in the required position; and the caution signal, which is shown when the track to which it refers is proper. The working of the switches and the signals for both lines is effected simultaneously by the hands and feet of one attendant. The engine-driver of every train, on approaching the junction, inquires of the switchman, and by his directions, has the signal in such a position as to give light in what direction he wishes to proceed. In addition to these fixed signals, the mechanical details of which are fully illustrated in the 'Railway Chronicle' of 1846, pp. 423 and 615, are those of the now familiar apparatus, for night and day signals, costs about £300; hand signals are made by the attendants and workmen upon the line either with the arms alone, with white, red, and green flags, or with the red and white flags, according to the day or night; when trains are passing through, white lamps attached to the front of the engine, and red lamps behind the last carriage of the train, are used as signals with every train, their number and relative positions serving to distinguish the trains destined for one line from those of another, wherever, as in the case of the Croydon, Brighton, and South-Eastern lines, the junction of different railways renders such distinction necessary. When the train is about to leave the station, the head, hung at the tail of the last carriage of a train, serves to indicate that it is to be followed by a special or express train; and a similar signal attached to the front of the engine of an express train acts as a special warning to keep the line clear of its approach.

In cases where the faggy state of the atmosphere might prevent the signals from being seen, and in other cases of emergency at night, the fog signals invented by Mr. E. A. Cooper are very useful. These are flat circular boxes of about two inches in diameter, filled with an explosive mixture, and furnished with a narrow slip of sheet lead, by which they may be released by the driver, on the approach of the train, to the subject of dispute between Mr. Dunn and Mr. Ellis, the patentee of another improved turn-table.

In the use of efficient signals great progress has been made within the last two years, which may be regarded as the most effective of all the inventions of this kind. The improvements suggested by experience, have been adopted on the lines of the South-Eastern, Brighton, and some other railway companies. The ordinary apparatus mounted at every station, and at each approach to stations of the more important class, consists of a semaphore pillar, near the main lines, of the arms mounted upon a common pivot near its upper extremity, either of which is capable of being moved independently of the other by means of a handle near the bottom of the post, so as either to hang vertically, in which position it falls into a slit in the post so as to be invisible; to project from it in a horizontal direction, or at an angle of 90°; or to assume a position intermediate between the vertical and the horizontal, projecting downwards at an angle of 45°. Each arm, whatever be its position, refers to its own particular point, that projecting towards the right referring to the right-hand track, and that projecting towards the left to the left-hand track, and when dropped within each other, so that the line to which it refers is clear, so that trains may pass safely; when projected horizontally, that a train is a short distance ahead, that there is some obstruction on the line, or that the station is occupied. In other words, when the pillar is or when projected at an angle of 45° that, owing to a train being ahead, though at a safe distance, or owing to some circumstance, any approaching train should slacken its speed, and any other signal, to be described hereafter, may also be employed. Such signals, with printed directions for their use, are deposited in every station, and are either fixed in such a manner as to be seen, or are adapted for use for the line on which they are adopted; and in case of an accident happening at night, several are fixed at intervals behind the point of obstruction, so as to give repeated warnings in an approaching train. When the line is clear they may be taken away and kept for future use. Such signals are used to stop all trains approaching a junction during a fog, until, by the mounting of the engine whistle and of a bell mounted for the purpose at the junction, the entire question of the plan of the signal-
largely and increasingly employed for passenger traffic, it becomes more and more necessary to work them at very high velocities. To this change we are inclined to attach considerable importance as a matter of safety, since, independently of the injury done to the road by throwing an enormous weight upon a single wheel, the increased weight of the engine and the wear and tear of the springs and axles, in order to increase their elasticity, the tendency of the engine to a dangerous rocking motion at high speeds is undoubtedly often increased by that circumstance; for if a disproportionate share of the weight of the machine is supported by a single wheel, it is not according to our former rule of thumb to say that we have a degree of play upon their bearing springs which may allow the motion we refer to to increase until the engine is thrown off the line, as there is some reason to believe has been the case in a single instance; and where no other method to increase their elasticity could be discovered for the engine leaving the rails. There can be no doubt that, with an equal amount of adhesion, a firmer and steadier bearing upon the rails may be obtained when the principal weight is divided between two axles when it is thrown upon one. The necessity for increased power, calling for the use of larger boilers and cylinders, is equal to the very general abandonment of that construction of engine in which the cylinders are placed at the bottom of the smoke-box, and the machinery is under the boiler; and a growing preference for those in which the cylinders are fixed outside the framing, and the power is conveyed to the wheels by external hand-rails and connections. Engines in which the machinery is thus arranged may be greatly enlarged in all their parts without raising the centre of gravity, the depth required for working the machinery and connecting the parts under the boiler being much less than if they have the further advantages of far greater strength in the axle, and of the whole of the machinery being easy of access for the purpose of examination and repair. The most of the new plant of the mechanical class, it is evident, may be examined and attended to while the engine is running; iron-plates, with hand-rails, being constructed along the sides of the frame of the engine. In some narrow-gauge engines boilers are used of 3 feet 9 inches diameter, being the largest dimension that the gauge will allow, and the sectional form has in a few instances been made slightly elliptical, the longer axis of the ellipse being placed vertically, in order to increase the height; but more generally increased power of the generating steam is sought by lengthening rather than enlarging the diameter of the boiler. The occurrence, in December, 1848, of a fatal accident on the Norfolk railway, with an engine on the recently-constructed line of Mr. Robert Stephenson, led to much discussion on the merits of this kind of engine; General Pasley having given evidence against their safety, which called forth a reply from Mr. Stephenson, in which he denies the assertion that the additional length of the boiler was inefficient on account of the distance of the farther end from the fire-box, and states that 'even with the longest tube yet introduced in locomotive engines, the temperature at the opposite end of the tube has been found sufficient to melt lead, while it is upwards of 300 degrees above the temperature of the water in the boiler; a fact which indicates that locomotive-engine builders have not even yet attained the length desirable so far as the working of the engine is concerned, but more especially as regards the difficulties occasioned by the expansion and contraction of the metal, they may have reached the utmost attainable length with the present construction of boiler. Mr. Stephenson does not state the precise length to which he has extended the boiler; but General Pasley observed that in his long engines it is four or five feet longer than in those formerly used. The distance between the front and fore axles of the engine to which the accident happened (a six-wheeled one), is 10 feet 6 inches; and from that to 12 feet 9 inches (in which, in his evidence before the Gauge Commissioners, Mr. Stephenson stated was, in his opinion, too long), is an increase of the length of bearing of most recently constructed engines for the narrow gauge; while 5 feet 6 inches was the length of bearing formerly employed on the London and Birmingham railway, with four-wheeled engines, though it had been extended to about 7 feet. Notwithstanding the great length of bearing, the fire-boxes of the longer engines referred to project beyond and overhang the hinder axle, so that the whole length of the bearings is about as much bearing upon the rails as in the original four-wheeled engines of the Birmingham line, with a bearing of only 6 feet 6 inches. Such large and powerful engines, by which it is anticipated that the present power of the engines obtained by that gauge may be safely attained, are necessarily much heavier than those of the older construction, though, perhaps, not so in proportion to their increased base. The Great Western company, how-
TRA 671

by the failure of which the vacuum was destroyed, and it became necessary again to transfer the traffic to the locomotive line. The London Bridge company (the new proprietors) are, however, considering the plan, and it is anticipated, a better valve will be fixed. In the mean time the continuation of the atmospheric line from Forest Hill to New Cross has been nearly completed, and arrangements have been made for the communication with the Croydon and Epsom lines. While the Croydon and Epsom line has been constructed, and is expected to be ready for traffic about Christmas, 1846, the atmospheric apparatus has not been laid upon it, and it is not expected to be completed for some time. The engine-in-charge, Mr. William Cubitt, having recommended that course on the ground that the atmospheric system, as now at work and in progress towards completion, is "to tend to a rapid increase of the power of locomotion," and during its progress, by being compelled to deal at tally-shops by means of tickets, while payments are only made once a month or even two months, this, by a system of credit, exposing the men to the temptation of spending carelessly, and of drunkenness, by receiving the balances due to them in an accumulated sum; that no provision is made for instruction, religious or merely educational, for the men or their children, and that there is, in consequence of all this want of care and want of principle on the part of the contractors, great want of cleanliness, discontent, disorder, drunkenness, and debauchery, on the line, the Directors of the Liverpool and Bury Railway are stated to have voted 1000l. a year for the special purpose of the care of the workmen, to obtain good lodgings and rooms for living in, and other comforts and conveniences.

As many millions of pounds must be spent, and many thousands of men employed in the construction of the railways which have already received the sanction of Parliament, it is deemed fit that the Legislature should interfere to protect the labourers, by suitable legislative measures, from the neglect and cruelty of those who employ them.

With respect to accidents which occasion loss of life or injury of limbs, either to workmen in the construction of railways, or to passengers in transit, Mr. Chadwick was examined by the Committee of the House of Commons before mentioned as to the provisions of the French law in such cases. Mr. Chadwick adduced the following provisions of the 'Code Civil':—

1. Article 1382. Every act whatsoever of the man who occasioned a damage to another, obliges him by whose fault it happens to repair it.

2. Article 1383. Every one is responsible for the damage he has caused, not only by his act, but by his negligence or by his imprudence.

3. Article 1384. A man is responsible not only for the damage occasioned by his own act, but also for that which is occasioned by the act of persons for whom he should answer, or of things which he has in his charge.

These provisions were not sufficiently understood by Mr. Chadwick, as they were understood to extend to companies, as well as to individuals; yet, by a law of July 15, 1843, on the general management of railways, a chapter was introduced to provide for the greater safety of railway passengers. The 22nd clause makes all owners or lessees of railroad responsible to individuals and the state, for injury caused by managers, directors, or any person employed in any capacity whatever in the working of them. Other clauses, from 16 to 21, enact penalties against those through whom accidents may be brought about, and for the mere violation of the regulations established by the king or prefects for the conduct of railways, even when no accident resulted therefrom.

BRITISH RAILWAYS

In the following tabular view of railway acts passed since 1840, supplementary to that given in P. C. p. xxvi, a large proportion of those described as new lines are merely for constructing branches or extensions of lines previously authorised; while among the amendments of the Acts which authorised deviations or alterations of lines previously sanctioned, many instances occur of the aggregate number of miles of railway sanctioned in each year, which must be taken out of the general view, as the various circumstances combine to render perfect accuracy unattainable. The aggregate length also needs some reduction to account for the cases in which an act passed in one session was sanctioned in another; and further, it must be mentioned that the figures which follow, indicative of the aggregate number of miles of railway sanctioned in each year, must be taken as an approximation of the facts, as the various circumstances combine to render perfect accuracy unattainable.
The figures however would not require any serious deduction from the figures given—

Amendments. Total. Length.
1801-1840 135 164 299 (See P. C., p. 261.)
1841 2 17 19 144 miles
1842 17 29 46 79
1843 10 13 23 91
1844 33 15 48 797
1845 104 16 120 2883
1846 227 43 270 4790

516 286 802 8649

By adding the above computation of mileage to those given in the former account, it will be seen that, in round numbers, without any deduction for abandoned schemes, about 11,600 miles of railway have been sanctioned by 516 acts of parliament between 1801 and the close of the session of 1846, of which upwards of 10,000 miles have been designed for working by locomotive engines for passenger and general traffic. Of this latter class about 1100 miles were open down to the close of 1840, while the length opened since that time down to the close of 1846, as reported year by year in the 'Companion to the Almanac,' where accounts of the more important lines are given, is about 1550 miles, making a total of at least 2650 miles in operation, besides many hundred miles in progress and on the eve of completion. Of the vast addition of 4790 miles (without deductions for a few lines to be made for joint use, although the acts give powers for their construction to two distinct companies) sanctioned in 1846, it is probable that several will prove, according to changes in the financial state of the country, be abandoned for a time; but numerous other schemes, several of them of considerable importance, are announced to be preparing for the session of 1847. Great however is the number of non-railway lines passed in the session of 1846, the schemes sanctioned by them form but a small proportion of the projects which were in agitation about the close of 1845. In such a matter it is difficult to arrive at every line of correct estimate; but it was stated in a great tabular statement compiled by Mr. Spackman, and published in the 'Times' newspaper of November 17, 1845, that the capital then invested in completed railways amounted to 70,680,877l., that that already laid out, and yet remaining to be expended, upon lines then under construction, amounted to 67,359,355l.; and that the capital which would be required to carry out 920 schemes, of which the estimates were then before the public, would be about 568,938,000l.; in addition to which mention is made of 643 projected companies, of which, as they had not yet registered their prospectuses, the proposed capital could not be estimated. These figures sufficiently indicate the extent of the railway mania of 1845. In compiling the following tables of English, Scotch, and Irish railways, we have inserted none but those for which acts have been passed, either absolutely or provisionally, and which have been constructed without parliamentary powers, and to economise space, we have made no reference to the amount of capital which each company is empowered to raise. Though compiled with the most care, they cannot be regarded as absolutely correct, and are to be depended upon, especially as regards the acts of 1846, because the alterations and curtailments sometimes made in a railway bill after it has passed the Select Committee by whom its details are reported to the House of Commons, and a variety of other contingencies, render it more difficult than could be conceived by any who have not made the attempt, to obtain authentic and correct materials for such a compilation; but from the precautions which have been adopted the compiler believes his statements to present the fullest and most accurate record yet issued of the railways completed, in progress, or sanctioned by act of parliament, in each division of the United Kingdom. Without regarding the acts passed to the contrary, it may be presumed that all lines sanctioned prior to 1846, if not marked as opened, are in progress; and even of those of 1846 several have been already (November, 1846) commenced. As the capital is not specified in each particular case, it may be well to state that the aggregate share-capital authorised to be raised under acts of 1844 for the construction of about 797 miles of railway was 11,121,000l., indicating an average cost of about 14l. per mile, but, of course, this is not the exact cost, as some lines were estimated for completed works, and the balance of capital and the estimated cost of such new lines as were granted to existing companies without any fresh powers for raising more, shows an aggregate estimate of 48,844,907l., for the construction of about 2883 miles of railway, indicating an average cost of about 16l. 10s. per mile. It is remarkable, considering the rapid progress of railway construction, that the amount of money sanctioned for new lines in 1844 was only 19,500l., and that the capital raised under existing railways was in 1845, only 91,165,500l., which, for about 4790 miles of railway, amounts to rather over 19,000l. per mile. These computations are, like that for 1844, calculated on the usual practice of borrowing one-third in addition to the capital. It will be observed, in reference especially to the new lines of 1846, how many of the recent projects are either promoted by, or for the benefit of, companies already established, or united with, existing companies; although in this point we cannot pretend to perfect accuracy, as the connexion of new projects with existing undertakings is not always mentioned in the acts themselves; while in many cases, where it is of a peripheral character, circumstances may lead to its being broken off. In some cases also parliament has refused to ratify agreements for amalgamation which had been formally concluded by the companies involved, although it may have been with some of the agreements here indicated. It was stated in the 'Railway Chronicle' of June 6, 1846, that out of 210 bills of which a classified list is there given, only 61 were for new or independent companies, and lines proposed for the purpose of establishing existing corporations as branches or extensions of, or auxiliary to, their own lines; and several lines which were granted as independent undertakings have since that time been purchased by established companies.

RAILWAYS OF ENGLAND AND WALES.

Aberdare.—The Talyllyn Railway, near Ynys Meryrick, to Aberdare; length, with a branch, 86 m.; act passed 1845; opened August, 1846.

Aberdare, Rhondda, Merthyr Tydfil, and Eastern Junction.—From the Aberdare station of the Midland Railway, through Nottingham, to Spalding and Boston, with branches. Main line to Spalding and Boston, via Lincoln, Grantham, and Linculn; Lines which are to be used, 594; Boston extension 194; Sleaford branch 9 m.; canal branch 1 m.; Boston harbour branch 2 m.; total length 894; act passed 1845; sold to the Great Northern Railway Company. The act confers powers to purchase the Nottingham and Grantham canals.

Ashburton, Newton, and South Devon.—A broad gauge branch from the South Devon Railway, near Newton Abbott; length 102 m.; act passed 1846. The South Devon Company has an interest in this line.

Ashby and Hastings.—See Brighton, Lewes, and Hastings; Rye and Ashford Extension.

Ashton Branches.—See Manchester and Birmingham, and Sheffield, Manchester-Lyne, and Manchester.

Ashton, Stalybridge, and Liverpool Junction.—Sold to the Manchester and Leeds Railway Company, from whose line it branched in 1846. In 1853 this company amalgamated with the London and Stalybridge in September, 1846. An act of 1846 authorises a branch of 14 m. to join the Manchester and Birmingham line in the vicinity of Ashton. Also Stalybridge Extension.

Austen and Gloucestershire. [C. P. C., p. 202.]

Aylesbury [C. P. C., p. 292.].—Sold to the London and Birmingham, and North-Eastern and North-Western Railway Company, whose line it joins at Bletchley. Length 16 m.; act passed 1845; opened November, 1846.

Birkenhead, Chester, and Wirral Railway. [C. P. C., p. 319.]

Birkenhead, Lancashire, and Cheshire Junction.—From the Chester and Birkenhead Railway at Hooton to the Manchester and Liverpool Railway at Stockport. Length 844; with branches amounting to 7s. m.; total length 46 m.; act passed 1846. The Company has agreed to amalgamate with the Chester and Birkenhead Railway.

Birmingham, Bristol, and Thames Junction.—See West London, Birmingham and Derby Junction [C. P. C., p. 292.].—Final line of the West London Railway. Length 1943; merged in 1845. Also Birmingham and Gloucester [C. P. C., p. 292.].—Main line, from the London and Birmingham Railway, at Birmingham, to Gloucester, and from the Bristol and Gloucester Railway at Gloucester 1 m.; length 1943; merged in 1845. Amalgamated with the Bristol and Gloucester Railway, and the united lines leased in 1846 to the Great Western Railway Company. Also authorised extensions at both ends of the line, and a branch at Stuke Prior, amounting together to 1 m.; and in 1846 the
Midland Company obtained an act for a branch from King's Norton to Bates Owen, length 59 m.; Birmingham, Leamington, and Manchester.—From the Grand Junction Railway at Aston, near Birmingham, to the Trent Valley Railway at Lichfield; length 141 m.; act passed 1846. Sold to the London and North Western Railway Company, 1847.

Birmingham and Oxford Junction.—Main line from Birmingham to join the Oxford and Rugby and Oxford, Worcester, and Wolverhampton Railway at Syston; length 22 m.; act passed 1846. To continue the broad gauge into Oxford and to the surrounding districts, and thus to compete with the London and Birmingham Railway. Act of 1846, but this line and the Birmingham, Wolverhampton, and Dudley, with which it is intended to amalgamate, must be laid upon the broad gauge and thrown into the break of gauge line occasionally at Penny Compton, where the Birmingham and Oxford Junction line joins the Oxford and Rugby, would impair the value of this short opening route. It is intended in next session to seek again for power to adopt the broad gauge. The Stratford-on-Avon Canal is to be purchased by the Oxford, Worcester, and Wolverhampton Railway Company, and made over to this company.

This and the Birmingham, Wolverhampton, and Dudley lines are to be sold to the Great Western Railway Company.

Birmingham, Wolverhampton, and Dudley—Main line from Birmingham to join the Stratford-on-Avon Canal at Long Stratton, length 93 m.; act passed 1846. See Birmingham, Wolverhampton, and Dudley Railways Company. Removed to 15 m.; act passed 1846—removal to complete the London, Brighton, and South Coast Company.

Birmingham, Wolverhampton, and Dudley—Main line from Birmingham to join the Stratford-on-Avon Canal at Long Stratton, length 93 m.; act passed 1846. See Birmingham, Wolverhampton, and Dudley Railways Company. Removed to 15 m.; act passed 1846. Power to operate a short line, to be amalgamated with the Blackburn, Darwen, and Bolton.

Blackburn, Darwen, and Bolton.—From Blackburn to Bolton; mileage 18 m.; act passed 1846. A second act, passed in 1846, provides for a shorter junction with the London and Birmingham Railway Company. See also Blackburn, Darwen, and Bolton—North-Western Junction.

Bolton and Wigan.—Main line, 12 m.; branch to Bodolus, 11 m.; branch to Blackburn Bridge, about 1 m. Total, with branches and adjoins, 17 m. The Lancashire and Yorkshire Railway Company have taken powers to purchase or lease this line.

Bolton and Leigh [P. C. p. 262.—Purchased by the Liverpool and Manchester Railway Company.

Bolton and Preston [P. C. p. 262.—Completed 1843. Amalgamated with the North Union.

Bolton, Manchester, and Warrington.—From the Syston and Peterborough line of the Midland Railway, near Stamford, to the Wirbach Branch of the Lynn and Ely (or East Anglian) Railway; length 5 m.; act passed 1846. Sold to the Great Northern Railway Company.

Brandling Junction [P. C. p. 262.—Purchased by the Newcastile and Leeds Junction Railway Company.

Brandon and Peterborough Extensions.—See Eastern Counties.

Bricklayer's Arms Branch and Station.—From the London and Great Western Railway at Keynsham, to a station and branch for West of England traffic, and a means of escaping the high tolls of the London and Greenwhich line; but the Croydon Company's share was subse-

quenty sold to the South-Eastern, who, in November, 1846, dis-
continued the running of passenger-trains to the Bricklayer's Arms terminus, retaining only goods and cattle traffic.

Bridgend. [P. C. p. 262.]

Bridgewater Navigation and Railway.—A short line of 2 m. to connect the operations of the Bridgewater with the Bristol and Exeter Railway; act passed 1845.

Bridgewater and Tunstall Canal, Railway, and Harbour.—The act for this line, 262.1 m.; act passed 1846; for the Tunstall Branch Railway Company, 1846; for the Tunstall Canal Company to make a railway from Bridgewater to the Bristol Channel at or near Stolford, about 94 m., with three short branches, is act passed 1846. The Tunstall Branch Railway and Tunstall Canal are intended to form portions of a projected line to connect the Bristol and Exeter Railway Company, and the London and Brighton, now London, Brighton, and South Coast Railway Company. Acts were obtained in 1846 for branches of 14 m. to Littlehampton, and 44 m. to Swayning.

Brightling Branches.—See Hall and Selby, and York and North Midland.

Bristol and Chichester.—Extension of the Shoreham Branch of the London and Brighton Railway, by Worthing, and between Littlehampton and Arundel, to Chichester. Length, 20 m.; act passed 1844; opened June, 1845. Purchased by the London and Brighton, now London, Brighton, and South Coast Railway Company.
Barnley Branch.—See Manchester and Leeds.

Camberwell.—See London and Southampton Railway.

Cambridge and Huntingdon.—See Eastern Counties.

Cambridge and Oxford.—See Bury and Hitchin.

Cromer's Greatbook Steam Coal and Limes Co., and Laughter.

From Mal-y-Manch to RHysafyrth, in the county of Glamorgan; length, 5 m.; act passed 1846. Joins the Oystermouth tramway at RHysafyrth.

Catterick, Timperley, and Margate Branch.—See South-Eastern.

Catterall and Whitehall, [P. C., p. 292.]—Purchased by the South-Eastern Railway Company, and now worked wholly by locomotives.

Chard Canal.—An act of 1846 authorises the Chard Canal Company to relaid the portion of their canal between Creech Saint Michael and Ilminster; length, 82 m. See Beegroe and Tiverton Canal, Railways, and Harbours.

Clampitt, and Great Western Railway [P. C., p. 292.]—Opened to Cirencester, May, 1841; to Gloucester, May, 1845. The remainder of the line to Cirencester forms part of the Bristol and Exeter Railway. Purchased by the Great Western Railway Company.

Chester and Birkenhead (P. C., p. 202.)—An act of 1845 authorises the company to open, from Birkenhead to Bebington. See Birkenhead, Lancashire, and Cheshire Junction.

Chester and Crewe (P. C., p. 262.)—Lengh, about 844 m. The original act, passed in 1844, differed the portion near the Menai Strait, which it was then proposed to cross by the existing suspension-bridge at 1845. In 1845, the act of the company, providing for a new bridge, which is to be made in the form of a wrought-iron tube or hollow beam, of about 460 feet span, so elevated that vessels may sail under it. See North Wales, and Shropshire Union.

Chester and Wolverhampton.—See Shropshire Union.

Clarence.—See North Staffordshire.

Clay-Cross and Newcast.—See Midland.

Cornwall Railway.—The Western, and Yarmouth and Norwich lines take its line. In 1845, the Eastern Counties Company made matters of amalgamation with the Northern and Eastern Counties, and became a corporation. of their finished line of about 29 miles from the Eastern Counties line at Stratford to Bishop's Stortford, with the Eastern Counties line on the London and Ware branch, and of the unfinished extension of about 10 m. from Bishop's Stortford to Newport. In 1846 the Eastern Counties Company obtained an act for extending this northern line by Cambridge to Ely, and thence eastward to Brandon, and westward to Peterborough, making altogether 72 m. of new line, of which the portion from Bishop's Stortford to Cambridge, Ely, and Brandon, was completed in July, 1845. The course of the Ely and Peterborough line was altered for a length of 29 m. under an act of 1846, in order to pass through with Grimsby, Humber and Hull Canal. See the original line completed in 1846. Another act of the same session authorised a line of 17 m. from Cambridge to Huntingdon. In 1846 the Eastern Counties Company obtained an act for a railway from London and Stratford stations; making a line from Epping, 10 m. long, and two branches, amounting altogether to little more than 12 m. long. See Eastern Counties.

Cromford and High Peak. [P. C., p. 202.]

Croydon and Epsom.—Length, 8 m.; act passed 1844; sold to the London and Southampton Railway Company. Projected as an atmospheric railway, but is to be worked for the present by locomotives. See Direct London and Portsmouth....

Cromer's Greatbook Steam Coal and Limes Co., and Laughter. [P. C., p. 262.]—Debdale and Stock.—From Mellor, in the parish of Minster, to Black Rock, in the parish of St. Michael, St. Minver Lowlands, Cornwall; length, 16 m.; act passed 1844. To be worked by horses, though some passenger-traffic is expected.

Debdoff Pier Junction [P. C., p. 262.]—Abandoned.

Devon, Bristol, and Dover Junction.—See Reading, Guildford, and Reigate.

Direct London and Portsmouth.—From the Croydon and Epsom Railway at Epsom to Portsmouth; length 604 m.; act passed 1844. This line lies near the line of the London, Brighton and South Coast Railway Company, as an atmospheric railway; but it now (November, 1845) appears probable that locomotive power may be adopted. The new line will be to the London, Brighton and South Coast, and London and South-Western Railway Companies jointly. See Reading, Guildford, and Reigate.

Ealingna, Greatfair. [P. C., p. 262.]—Amalgamated in 1846 with the Llwyth Valley Railway; and may probably be converted into a locomotive line.

Denzel and London and Birmingham.—From the London and Birmingham Railway near Leighton Buzzard, length 32 m., act passed 1845. To be leased or sold to the London and North Western Railway Company.

Dorking Junction [P. C., p. 262.]—Length, from the Selsham Railway to the Staneh and Tye Railway (both of which were made without acts of parliament), nearly 5 m. Purchased by the Newcastle and Darlington Junction Company. Purchased by the Newcastle and Darlington Junction Railway Company, and to be adopted by the Company.

East and West India Docks and Birmingham Junction.—From the East and West India Docks to the London and Birmingham railway at Camden Town; length, 8 m.; act passed 1846. Promoted to be a branch of the London and Birmingham Railway Company.

East and West Yorkshire Junction.—From Knaresborough to the Great North of England Railway about 14 m. from York; length, barely 14 m.; act passed 1846.

East Anglian.—Under this title it is proposed to amalgamate the Lynn and Ely, Lynn and Dereham, and Ely and Huntingdon Companies and to lease them to the Eastern Counties Railway Company.

East Lancashire (originally Manchester, Bury, and Rosendale and Accrington.)...[P. C., p. 262.]—Opened from London to Colebeater, 514 m.; in March, 1843, and the remainder of the original parliamentary line abandoned; the Eastern Union; Ipswich, Bury, and Accrington Union and the North and South Railway.

East London.—See London and Southampton Railway.

East Midland Counties and St. Andrew's.—[P. C., p. 262.]—Opened from London to Colebeater, 514 m.; in March, 1843, and the remainder of the original parliamentary line abandoned; the Eastern Union; Ipswich, Bury, and Accrington Union and the North and South Railway.

East Anglian.—[P. C., p. 262.]—From Stratford to the mouth of the river Lea; length, 24 m.; act passed 1844; opened April, 1846. Sold to the Eastern Counties, which see. See also North Woolwich.

Eastern Union.—[P. C., p. 262.]—From Colebeater to Ipswich; length, 17 m.; act passed 1844; opened June, 1845; from Colebeater the line was made by the Eastern Counties, but the land being theirs; but this portion has been sold to the Eastern Counties Company. Sold to the Eastern Counties Company.

Ely and Huntingdon.—Length, under the original act of 1845, 26 m.; but its line as afterwards shortened by an act of November, 1845, the Eastern Counties line about 1 m. from Ely. See East Anglian.

Epsom and Edenbridge.—The Eastern Counties Company obtained an act for a railway from Epsom to Edenbridge, with the line thence to East Grinstead, and to South Coast Railway Company. See Edenbridge and South Coast, and London and South-Western Railway Companies jointly. See Reading, Guildford, and Reigate.

Epping.—[P. C., p. 262.]—Amalgamated in 1846 with the Llwyth Valley Railway; and may probably be converted into a locomotive line.

Ernesoth Valley.—[P. C., p. 262.]—From the Midlothian Railway at Sawley to the Mansfield and Phixton Railway; length, 119 m.; act passed 1845; sold to the London and North Western Railway Company. For extensions and branches see Midlothian.
to the Bristol and Exeter. To open December, 1846. An act for the extension at the Grey Inn and Bagrrudge Wells roads, north of the Middlesex House of Correction. The proprietary is formed by amalgamating with the London and York, and the rival direct Northern Railway Company. See

Foster and Emmouth.—Length, with a very short branch at Topsham, 104 m.; act passed 1846.

Fleetwood, Preston, and West Riding Junction.—From Preston to Clitheroe; length, nearly 16 m.; act passed 1846. See Preston and Clitheroe.

Forest of Dean (formerly Bull Hill).—[P. C. p. 263.]

Furness.—Original line, under an act of 1844, intended to connect iron-mines near Dalton Ladle, and slate-quarries at Kirkby- Ireth, with the coast at Barrow and Rampside; length, 158 m. Opened in June, 1846, and passenger-traffic worked in connexion with steamers from Fleet harbour to Fleet Creek. As act of 1846 authorised a branch from Fleeton to Broughton, only 4 m. from Dalton to Ullswater, and branches to the Whirrige and Butts iron-mines, making a total of 9 m.

Gosport and Chichester.—[P. C. p. 263.]

Gosport and Dean Forest.—From Gosport to the Monmouth and Hereford Railway, and to the South Wales Railway at Aylestone; length, nearly 6 m.; act passed 1846. To be sold to the Great Western Railway Company.

Great Western [P. C. p. 263.—] Completed June, 1841. The company has purchased the Burts and Hunts, the Cheltenham and Great Western, the Montmorency and Hereford, and the Oxford and Rugby lines. See the Burts and Hunt; and possess the Oxford Branch, which see. See also, for further connections, Birmingham and Oxford Junction; Birmingham, Wolverhampton, and Dudley; Bristol, the Gloucester and Hereford, and Rotherham; Great Western and Uxbridge; Great Western and Wycombe; Oxford, Winchester, and Wokingham; Fort- burg; South Devon; South Wales; West Cornwall; West Lon- don; and Wilts, Somerset, and Weymouth.

Great Western and Oxford.—Johns the Great Western line at West Drayton, where over 24 m.; act passed 1846.

Great Western and Wycombe.—From the Great Western line at Maidenhead to High Wycombe; length, over 94 m.; act passed 1846. To be sold to the Great Western Railway Company.

Greenwich and Gravesend.—See South-Eastern.

Guildford Extension, Portsmouth, and Fareham.—Projected as the Guildford, Chichester, Portsmouth, and Fareham Railway; the original line, under an act of 1846, only to the London and Portsmouth, the act passed in 1846, sanctions only a line of about 4 m. from Guildford to the Direct London and Portsmouth at Fareham, to be sold to the Great Western Railway Company. The power to make these has been sold to the London and South-Western Railway Company.

Guildford Junction Railway.—The London and South-Western Railway; length 6 m.; act passed 1844; opened May, 1845. Sold to the London and South-Western Railway Company.

Harrodsfield, and Sheffield—See North Staffordshire.

Hay [P. C. p. 263.]

Heathfield and looking to the North of London and South- Western Railway Company.

Huddersfield and Manchester Railway and Canal.—A railway from the Sheffield, Ashton-under-Lyne, and Manchester to Stalybridge to the Manchester and Leeds line at Kirkcudbright, 214 m.; with a branch of 1 m. to Delph; act passed 1845. The Company to purchase the Huddersfield and Sir John Bramley’s canals. Acts of 1846 authorise a deviation at Huddersfield; a branch of 14 m. from Cooper Bridge; and a branch of 4 m. to the Manchester, Ashton-under-Lyne, and Manchester and Sheffield Railway Company at Oldham. The whole of the line passing from York to Darlington, 440 m. March, 1841; and the remainder of the parliamentary line abandoned, the Newcastle and Darlington Junction has been purchased by the Newcastle and Darlington Junction Company, the name of which, under an act of 1846, which sanctions the pur- chase, is established in the Stock Exchange. Under an act of 1845, a branch of 9 m. has been formed from a few miles south of Darlington to Richmond, which was opened in September, 1846; and under acts of 1846 the York and New- castle Railway Company have power to make branches to Bedale, 7 m.; to Boroughbridge, 62 m.; and from Thirsk to Malton, 204 m.; with subsidiary branches of 5 m. to Helmsley, 6 m. to New Malton, and 23 m. to Selby.

Great North of England, Clarence, and Hartlepool Junction [P. C. p. 263.—] Acts of 1843 and 1845 authorised new branches of 20 m. from the Great Northern Railway Company to the Seaboard, and sold to the Hartlepool Dock and Railway Company, and has merged with it in the York and Newcastle. Opened October, 1846, in connexion with a re-opening of the Hartlepool line as a branch of the York and Newcastle.

Great North of England and Richmond.—See Great North of England and Richmond.

Great Northern (originally London and York).—Main line from King’s Cross, London, by Hitchin, Biggleswade, Huntington, Peterborough, Grantham, Lincoln, Newark, Grantham, Don- caster, and Selby, to the Great North of England Railway at or near the York station, nearly 186 m.; loop or diverging line from near Grantham, to Lincoln, Grantham, Louth, and Grimsby, 66 m.; branch to Lodge, near 8 m.; minor branches and junctions, about 64 m.; total, 274 m. The act of 1845, the subject of a separate act, is a branch of the Great Northern, and several others are projected. The company also proposes to...
Launceston and Victoria [P. C., p. 263].—Abandoned.

Leeds and Bradford.—Original line, under an act of 1844, from Launceston, along the valley of the Aire, and by Shipley, to Bradford, 138 m.; with a branch of 14 m. to the North Midland Railway. In July, 1846, an act of 1845 authorises an extension from Shipley to Colne, with a branch to Haw-
tworth, together 393 m.; and acts of 1846 provide for an alteration of the line to join the West Riding Union Railway at Bradford. After agreeing to amalgamate with the Manchester and Leeds, an arrangement was made in 1846, to supersede it by a perpetual lease of the whole undertaking to the Midland Railway Company.

Leeds, Dewsbury, and Manchester Junction.—From the Leeds and Bradford line, a branch is now projected to Dewsbury, and thence to Huddersfield, being a main line of 16 m. with branches amounting to 4 m. The line from Hudders-
fied, however, is only to be made if the Hudders-
field and Manchester Company fall to complete their act passed 1845. A second act of 1846 provides for deviations at Dew-
and mineral traffic; the Holden Clough branch of 5 m. to the Birstall branch, nearly 3 m. To be leased to the London and North-Western Railway Company.

Leeds and Thirsk.—Main line 394 m.; branches to Knares-
borough Junction Railway at Whalley, a branch of over 6 m. to Westmor-
den; and an amalgamation with the Manchester and Leeds. Acts of 1846. The connection of this line by the Midland Railway Company, and confer on the purchasers power to alter 14 m. of the line, and to make new branches to Leicester, 32 m.; to Burton-
upon-Trent, 27 m., and on the northwest side of the city, nearly 23 m. Liskeard and Caradon.—Length, main line, 64 m.; branch to the Cheesefaring, 24 m.; act passed 1845; partly opened 1844. For mineral traffic. Worked by gravity and horse-power. See Cornwall.

Leicester and Syston.—[P. C., p. 263].—Acts of 1846 confirm the purchase of this line by the Midland Railway Company, and confer on the purchasers power to alter 14 m. of the line, and to make new branches to Leicester, 32 m.; to Burton-
upon-Trent, 27 m., and on the northwest side of the city, nearly 23 m. Liskeard and Caradon.—Length, main line, 64 m.; branch to the Cheesefaring, 24 m.; act passed 1845; partly opened 1844. For mineral traffic. Worked by gravity and horse-power. See Cornwall.

Liverpool and Bury.—Original line, under an act of 1845, from Liverpool to Wigan, Bolton, and Bury, 24 m. Acts of 1846 authorise an extension of 6 m. to Tythe Barn Street, Liverpool; a branch of nearly 1 m. from the New Springs branch to the North Kensington branch; and an amalgamation with the Manchester and Leeds. Acts of 1846. The junction line referred to in the above act, 14 m., was completed in March, 1844. An act of 1845 authorises a new entrance into Liverpool, and a branch to join the Manchester, Bury, and Rossendale line at Gorton; 7 m.; act passed 1846. Another 73 m. of the same session ratified the amalgamation of the Liverpool and Manchester, with its connections, the Bolton and Leigh and Ken-
on; and the St. Helens line, with which it is now merged in the London and North-Western.

Liverpool, Manchester, and Newcastle-upon-Tyne Junction.—Main line, from the Leeds and Bradford Railway at Elslack, to the Richmond branch of the Great North of England Railway at Serton, 474 m.; branch to Hawes, over 9 m.; act passed 1846. This undertaking comprises the main line of the Lancashire and North Yorkshire Railway; and, in the Hawes branch, a portion of that projected by the Liverpool, Manchester, and Newcastle upon-
Tyne Junction Railway at Whalley, a branch having been cancelled while before parliament. The Hawes branch, being identical with part of the Yorkshire and Glasgow Union projected line, is not to be made if that line be, as intended, constructed by a new Northern Union Counties Railway Company, which see. The capital is partly subscribed by the Manchester and Leeds Railway Company.

London, Ormskirk, and Preston.—Main line, from the Liverpool and Bury Railway at Walton-on-the-Hill to the North Union Railway at Penwortham, 231 m.; branch to the Blackburn and Freckleton Railway, 6 m., including the Lydiate-Gate branch of 3 m.; branch to near the junction of Walton Street and Regent Road, Liverpool, nearly 1 m.; total 29 m. Amalgamated with the South Eastern Railway Company.

Lowelly [P. C., p. 264].—The total length of this line and its branches, according to evidence before the Gauge Commissioners (1843), was 9 m.; act passed 1846. As it joins the South Wales Railway, this line is laid on the broad gauge. The company has amalgamated with the Duffryn-Llwydiarth and Newport-Cr.cf Railway Company.

Manchester, Blackpool, and Lynn.—[P. C., p. 264].—The act of 1843 this company has made a branch of 4'7 m. from Bithorn, by Northampton, to Peterborough, which was opened in June, 1845. It also passed the Aysgirth and Crosby Valley, and the Warwick and Leamington Union Railways; and, under an act of 1845, has amalgamated with the Grand Junction and Manchester and Birmingham Railway Companies, incorporating the numerous lines and connections of the latter under the comprehensive title of the London and North-Western Railway, which see. Other acts of 1846 confirm certain arrangements with the Bir-

London and Blackwall (formerly Commercial) [P. C., p. 264].—Extension line of 5 m. to near Fenchurch Street opened 1845-August. In 1846 gives a new line from Stepney to Fenchurch Street, to accommodate the traffic expected from the Eastern Counties Railway by the London and Blackwall Extension Company, which see, worked by the London and Blackwall Company. The East and West India Docks and Bir-

London and Brighton [P. C., p. 264].—The main line, of 419 m., from near Croydon to Brighton, was completed in Septem-
ber, 1841; the shortest branch, of 54 m., in May, 1846. The other branches mentioned in P. C. were abandoned, but are replaced by branches granted in 1846 in connection with the Brigh-
ton, Lewes, and Hastings. The line between Croydon and Reigate or Redhill, is worked by the Brighton and South-Eastern Companies jointly, one-half of its cost having been repaid to the former before 1849. The line maintains the southern half of that portion of the line. The Lon-

London and North-Western.—[P. C., p. 263].—The main line, from Liverpool to London, 370 m.; branch to meet the Croy-
don, Brighton, and South Coast Railway Company, which see.

London, Brighton, and South Coast.—This is the new name of the London and Brighton Railway Company, with its branches to Hastings, Chichester, and Portsmouth, as above mentioned, con-

London and Croydon [P. C., p. 264].—The Company have purchased the Croydon and Epsom Railway (which see), and are (1846) laying down in connection with it an atmos-

tropic line alongside of their original works, under the au-
tority of an act of 1845. Acts of 1846 authorise the con-

London and Greenwich [P. C., p. 264].—The line was widened from London Bridge to Croydon, and the London, Greenwich and New Year's Green Company, the new portion being brought into use, 1 May, 1842. Since that time a lease for 99 years has been granted to the South-Eastern Railway Company, who obtained powers in 1845 for a further widening, and in 1846 for a line from the
Greenwich Railway to Gravesend. The London Bridge station was formed at the expense of the London, Brighton, and Croydon, and South-Eastern Railway Companies.

**London and North-Western.—** Under this new title, by an act of the 16th and 17th of Geo. IV., cap. 105, dated 27th of July, 1825, the London and Birmingham Railway Companies, with their respective connections, are amalgamated. The aggregate share-capital of the united company, according to the act, was 17,242,301l.; and the amount of loans, 5,747,000l.; making a grand total of 22,989,301l.; which, however, will be greatly extended when the capital for the various new lines was granted in 1846 to the North-Western Railway Company. As well as these numerous additional purchases and amalgamations proposed shall be carried into effect. Besides the lines referred to as connections, there are the several companies now united under this title, and the London and North-Western Company possess shares, or have some interest in the Chester and Holyhead, Lancaster and Carlisle, and Caledonian Companies; and Leeds, Dewsbury, and Manchester.

**London and Portsmouth.—** See Direct London and Portsmouth.

**London and South-Western (formerly London and Southampton)** [P. C. p. 304.—Act of 1844 authorises a branch of 3½ m. from Bishoptoke to Salisbury, which is (November, 1840) nearly completed, and a short extension from the Nine Elms station, which has not been carried into effect. An act of 1845 authorises an extension of about 9 m. from Nine Elms to a point near Watford; and an extension of another 9½ m. from the junction with the Midland Railway at Salisbury, with a subsidiary branch of 1½ m. to join the Bishoptoke and Salisbury branch; a branch of 6½ m. from the junction with the South Western Railway at Salisbury, from the Guildford Junction line, near Guildford, to Farnham and Alton; and a branch of 1½ m. to Hampton Court bridge. The Gypsum Branch, opened in February, 1842, is incorporated with this undertaking. See also Direct London and Portsmouth, Guildford Junction, Guildford Extension, Farnham, and Portsomth; Richmond; and Southampton and Dorchester.

**Lovelace Railway and Harrow.—** From Lovelace to the Yarmouth and Norwich Railway at Reeds Hall; length 11 m.; act of 1841; passed 1843; part opened October, 1846. Agreement to amalgamate with the London and South-Western Company, under the name of the Great Eastern Railway, passed 1844; sold to the London and South-Western Railway Company.

**Lynn and Egg Railway.—** Main line, from the Lynn and Dereham Railway at Lynn, to the Eastern Counties Railway at Egg, 26½ m.; branch from Reedham to the Great Eastern Railway, about 2½ m.; length 29 m.; act passed 1842; open to traffic 1845.

**Lynn and Egg Railway.—** Main line, from the Lynn and Dereham Railway at Lynn, to the Eastern Counties Railway at Egg, 26½ m.; branch from Reedham to the Great Eastern Railway, about 2½ m.; length 29 m.; act passed 1842; open to traffic 1845.

**Lynn and Egg Railway.—** Main line, from the Lynn and Dereham Railway at Lynn, to the Eastern Counties Railway at Egg, 26½ m.; branch from Reedham to the Great Eastern Railway, about 2½ m.; length 29 m.; act passed 1842; open to traffic 1845.

**Lynn and Egg Railway.—** Main line, from the Lynn and Dereham Railway at Lynn, to the Eastern Counties Railway at Egg, 26½ m.; branch from Reedham to the Great Eastern Railway, about 2½ m.; length 29 m.; act passed 1842; open to traffic 1845.

**Lynn and Egg Railway.—** Main line, from the Lynn and Dereham Railway at Lynn, to the Eastern Counties Railway at Egg, 26½ m.; branch from Reedham to the Great Eastern Railway, about 2½ m.; length 29 m.; act passed 1842; open to traffic 1845.

**Lynn and Egg Railway.—** Main line, from the Lynn and Dereham Railway at Lynn, to the Eastern Counties Railway at Egg, 26½ m.; branch from Reedham to the Great Eastern Railway, about 2½ m.; length 29 m.; act passed 1842; open to traffic 1845.
The length to branch, m.

An act of 1846 authorises an extension of 224 m. from the Deringham branch (see Act) for leasing purposes for nearly 61 m. to Blakeney, total 592 m.; and another sancctions the purchase or lease of the Lowestoft Railway, Harbour, and Navigation Company. The Newcastle-upon-Tyne–Darlington Junction Railway, and is to be continued by agreement for joint use. It was passed 1846. This undertaking is formed by the consolidates the York and Carlisle and Yorkshire and Glasgow projected.
Ruis, adopting the course of the latter from Thirk to Clifton and a portion of the Amendment to Teyho. 

Northern Union.—See Newcastle and Darlington Junction. 

Norwich and Brandon.—By the original act of 1844 this was to be a main line of 38 m., with a branch, 3 m., to Thetford; but under an act of 1845 the main line was diverted to pass through Thetford, making the length about 36 m. Opened July, 1846. 

Amalgamated with the Yarmouth and Great Yarmouth Railway, which see. 

The act of 1845 allows a branch of 1 m. from Wymondham to East Dereham. 

Norwich and the Yarmouth Railway. 

Oxford and Bletchley Junction.—See Buckinghamshire. 

Oxford Branch.—From the Great Western Railway at Didcot to Oxford, opened June, 1844. Made by the Great Western Railway Company. 

Oxford and Rugby.—From the Oxford branch of the Great Western Railway at Oxford to the London and Birmingham and Midland Railways at Rugby; length 503 m.; act passed 1845. 

Sold to the Great Western Railway Company, who are constructing it as a broad-gauge line. See Birmingham and Oxford Junction Railway, and also the account of the gauge controversy p. 665. 

Oxford, Worcester, and Wolverhampton.—The original act passed 1843 for a main line of 259 m. in extension of the Oxford branch of the Great Western Railway, with the Worcester branch, 13 m.; the Stock branch, 4 m.; the Stonebridge branch, 1 m.; and the Compton branch, 3 m. Act sanctioned at 7 October, 1845; and in 1846 they obtained an act for extending the line by 10 4 m. An act of 1846 provides for some alterations in the line, and a branch of 8 m. to Stratford-on-Avon, one of 4 6 m. to Wilmcote, and a connection of 4 m. at Dreish, making together 19 m. of new line. The line is being constructed for the broad gauge, and under a guarantee from the Great Western Railway the options are subject to the condition of laying additional rails where the connection with narrow-gauge lines may render it necessary in order to avoid a break of gauge. (See also the gauge controversy, p. 665.) The company have leased the Stratford and Moreton Railway; and the act of 1846 gives power to purchase the Stratford-on-Avon and Stonebridge branches, the portion of which line is to be leased to the Birmingham and Oxford Junction Railway Company. 

Oystermouth. [P. C. P. 264.] See South Devon. 

Portishead and South Shields.—A private company, formed about 1831 or 1832, constructed, without the authority of an act of parliament, an extensive line called the Stockbridge and Tyne Railway, running for about 34 m. from South Shields, through the northern part of the county of Durham, to Stanhope, which was worked, at least partially, by locomotive engines, and used principally for coal traffic. It proved an unsuccessful speculation; and in 1832 a new company was incorporated by act of parliament for working a portion of the line, the old company being dissolved. In 1834, 1835, 1836, and 1837 acts were obtained for extending the Portishead and South Shields Railway Company, obtained an act for widening a part of their line, and making a new branch of 4 m. to the Bramley Ghyll line. The undertaking was completed by the whole undertaking has been consolidated with the Newcastle and Darlington Junction, now the York and Newcastle Junction Railway Company. 

Portland. [P. C. P. 264.] 

Portbury Pier and Railway.—The act, passed in 1846, is for making a pier at Portbury, and a railway of nearly 6 m., with a branch of nearly 1 m., to connect it with the Bristol and Exeter line near Bristol; to be laid on the broad gauge, and may be leased to the Great Western or Bristol and Exeter Railway Company. 

Portsmouth.—See Brighton and Chichester, Portsmouth Extension; Direct London and Portsmouth; and Guildford Extension, Portsmouth, and Fareham. 

Potteries Line.—See North Staffordshire. 

Preston and Wyresdale. [P. C. P. 265.] An act of 1845 authorizes branches to Blackburn, 32 m.; to Lytham, about 4 m.; and to Lytham Dock, under 2 m. These were opened in April, 1846. An act of 1846 sanctions the amalgamation of the Preston and Wyre Railway, Harbour, and Dock Company with the Manchester and Leeds Railway Company. 

Reading, Guildford, and Reigate.—Length, main line 454 m., and two branches at Yarnham, where the line joins the London, Brighton, and South Coast Railway, and the line of 43 m., which this line, which is part of the projected Devizes, Bristol, and Dover Junction Railway, is to be leased to the South-Eastern Railway Company. 

Regent, Guildford, and Reigate. —Length, main line 454 m., and two branches at Yarnham, where the line joins the London, Brighton, and South Coast Railway, and the line of 43 m., which this line, which is part of the projected Devizes, Bristol, and Dover Junction Railway, is to be leased to the South-Eastern Railway Company. 

Regent, Guildford, and Reigate. —Length, main line 454 m., and two branches at Yarnham, where the line joins the London, Brighton, and South Coast Railway, and the line of 43 m., which this line, which is part of the projected Devizes, Bristol, and Dover Junction Railway, is to be leased to the South-Eastern Railway Company. 

Retail and Wigan.—See North Union. 

Preston and Wyre. [P. C. P. 265.] An act of 1845 authorizes branches to Blackburn, 32 m.; to Lytham, about 4 m.; and to Lytham Dock, under 2 m. These were opened in April, 1846. An act of 1846 sanctions the amalgamation of the Preston and Wyre Railway, Harbour, and Dock Company with the Manchester and Leeds Railway Company. 

Reading, Guildford, and Reigate. —Length, main line 454 m., and two branches at Yarnham, where the line joins the London, Brighton, and South Coast Railway, and the line of 43 m., which this line, which is part of the projected Devizes, Bristol, and Dover Junction Railway, is to be leased to the South-Eastern Railway Company. 

Rotherham, Barnsley, Wakefield, Huddersfield, and Goole.—Main line, rather over 21 m.; Silkstone branch, nearly 2 m.; Dodworth branch, 3 m.; total 26 m.; act passed 1846. The portion north of Barnsley is to be leased to the Manchester and Leeds Railway Company, and the remainder to the South Yorkshire Coal, Railway, and Canal Company, who, having failed to obtain their act in 1846, are applying for leave to sanction this arrangement in 1847. 

Sheldon Tunnel.—See Wear Valley. 

Shglesby and Cole.—See Leeds and Bradford. 

Shrewsbury and Birmingham.—The act obtained by the Shrewsbury and Birmingham Railway Company in 1846, was for a main line of 291 m. from Shrewsbury to Birmingham, with a branch or fork of 7 m. to the Abbey Foregate, Shrewsbury, and
a branch of 4 m. to Coalbrook Dale, making a total of 34 m.

These lines form part of a much more extensive scheme, the objects of which are to be attained by means of complicated arrangements—Shrewsbury, Wolverhampton, and South Staffordshire Junction Railway Company (with which this company is amalgamated or united for the purpose of making the line granted to the formation of a railway between Shrewsbury and Wolverhampton, and a large part of the line granted to the other company; as between Tetshall and Wolverhampton), the Birmingham, Wolverhampton, and South Staffordshire Junction Railway Company, and the Shropshire Union Railways and Canal Company. All of the lines granted to these companies may be regarded as parts of a system of communication connected with the London and North-Western Railway.

Shrewsbury, Wrexham, and Chester Junction—From Shrewsbury to the North Wales Mineral Railway at Cefn Mawr, with branch to Oswestry; length 233 m.; act passed 1845. Acts of 1846 sanction an extension of the main line from Shrewsbury, and deviations at Shrewsbury and other places amounting to 8½ m.; branches of 6 m. to Crich Heath, and of nearly 7 m. to We; and the amalgamation of the whole undertaking with the Act which sanctioned the Great Western Railway, which partly overlaps the Shrewsbury and Chester Railway.

Shrewsbury and Stafford—See Shropshire Union Railways and Canal. Length, main line from Shrewsbury to Wolverhampton, rather over 291 m.; branch at Shrewsbury, nearly 7 m.; act passed 1846. In 1861 an act was passed for the amalgamation of the Shrewsbury and Birmingham, a considerable portion of this line will be abandoned, the two companies uniting to execute certain portions of the works.

Shropshire Union Railways and Canal.—Three acts were obtained in 1846 by a company with the above title, authorising, respectively, the formation of a railway of nearly 46 m., from the Chester and Crewe branch of the Great Western Railway, at Calveley, to Wolverhampton, called the Chester and Wolverhampton Railway, to purchase the line of the Ellesmere Canal, and to convert part of it into a railway; the formation of a main line of railway of nearly 60 m. from Newtown, in the county of Montgomery, to Shrewsbury; and the formation of a main line of railway of rather over 39 m. from Shrewsbury to Stafford, with a branch of 1½ m. to Stone, including power to purchase the Shrewsbury Canal. The aggregate length of the above lines is rather over 105 m.; but the company are restricted from making that portion of the last-mentioned line, which lies between Shrewsbury and Wellington, in case either the Shrewsbury and Birmingham or the Shrewsbury, Wolverhampton, and Staffordshire Junction Company should obtain their act, which both did, although, as explained under Shrewsbury and Birmingham, only part of the scheme of each is to be carried into execution. Arrangements have been made by the two undertakings for the leasing of the whole of the Shrewsbury and Chester Junction; and the amalgamation of the company with the London and North-Western Railway Company.

Shrewsbury and Chester Junction Railway Company is an interesting branch of the Shropshire Union System. [F.C., p. 265.]

South Devon—From the Bristol and Exeter Railway at Exeter to Plymouth; length, about 51½ m., exclusive of a branch of about ½ m. to Mill Bay, and an alteration of about 2 m. of the Plymouth and Dartmouth Railway, which the company are empowered to lease or purchase; act passed 1844; gauge 7 ft. Intended for working by atmospheric power; but 15 m., from Exeter to Tegitmachen, opened in May, 1846, with locomotive engines. An act of 1846 sanctions a branch of 5 m. from Aller, near Newton, to Torquay; a deviation of the main line near Newton; and several alterations in connection with the towns of Plymouth and Torquay. The power company proposes to subdivide this line under the Great Western, Bristol and Exeter, and Bristol and Gloucester Railway Companies, which are empowered to lease the company's line. The Devon Company also proposes an interesting branch from the Ashburton, Newton, and South Devon and the Cornish lines.

South-Eastern—[F. C., p. 265.].—The main line, which was extended to the Dover end in 1840, opened throughout in February, 1844. A branch of 10 m. from Paddock Wood to Maidstone, made under an act of 1843, was opened in 1844. In 1844 the company obtained an act for a branch of 4 m. to Folkestone Harbour (which they had purchased), which has since been completed; and for a branch of 3½ m. to Canterbury, which was completed in 1846. In September, 1845, they opened the greater part of the Tumbling Wells branch, from near Mumford, which was made in anticipation of an act of parliamant and completed in 1846. In 1845 they obtained acts to sanction the last-mentioned branch; to enable them to alter and extend the Canterbury, Ramsgate, and Margate branch, and for the formation of two lines from Ramsgate to the Channel, in order to enable them to purchase the Canterbury and Whitstable Railway; and to widen the London and Greenwich Railway, which they propose to extend to Ramsgate; and they have also obtained acts for enlarging the station at Ashford, as a central locomotive depot; for making a railway of 2½ m. from the London and Greenwich Railway, which they propose to extend to Ramsgate, and for the formation of a branch to Ramsgate Park; for a line of 25½ m. from their Tumburidge Wells branch to join the Rye and Ashford extension of the Brighton, Lewes, and Hastings Railway near Hastings, with a running line of 6 m. towards Rye; for a branch of 1½ m. from Rye to Rye Harbour; and for authorising the purchase of the Gravesham, Dartford, and Gravesend Railway, about 15 m. from Dartford Junction.—The Brighton, Lewes, and Hastings Railway, which is amalagamed, as the South Staffordshire Railway, a branch of 8½ m. to Darenth; a branch of 32½ m. to Mote End; a branch of 29 m. to Chilham; a branch of 24½ m. to Willingham, and a branch of 12½ m.; act passed 1846. See Birmingham, Wolverhampton, and Dudley.

South-Western Railway Company.—Proposed as a broad-gauge line in connection with the Great Western Railway, to commence by a junction with the Cheltenham and Great Western Union Railway at Stourbridge; or, were objections to the proposals to the Severn Railway, an act of 1846 was to a main line of 160 m. from Chesham to Flasbury and Pembroke Dock, with a branch of 27 m. to Monmouth. An act of 1847 provides for an extension of 12 m. from Chesham to join the Gloucester and Forest of Dean Railway at Haflow Farm; a branch of rather over 14 m. to Swansea, and a branch of 6½ m. to Haverfordwest, making in the whole 185 m. of new line; and also sanctions several deviations, amounting to 233 m., on the original main line and branch; but owing to objections to the proposed crossing of the Severn, it seems to the efforts to obtain a direct connection with the Great Western line by means of a bridge or tunnel at Hock Crib. The undertaking is leased to the Great Western Railway Company, with provision for a future amalgamation. See also Bristol and South Wales Junction Railway—Lagan Valley; Treby, Saundersfoot, and South Wales; and Vale of Neath.

South-Western—See London and South-Western.

South Yorkshire—See Sheffield, Rotherham, Barnsley, Wakefield, Huddersfield, and Barnsley.

Southampton and Dorchester.—Length, 60 m.; branch to Poole, 2½ m.; act passed 1845. Gauge, 4 ft. 8½ in.; to be leased to the London and North-Western Railway Company. [F.C., p. 265.]

Stratford-upon-Avon—Branch of the Great Northern Railway in the parish of Ufford, Northamptonshire, to the loop-line of the same railway in the parish of Crowthorne, Berkshire; length, 2½ m.; act passed 1846. Sold to the Great Northern (late London and York) Railway Company.

Stoke-on-Trent—See Stafford and North Stafford.

Stockton and Darlington.—The line, 8½ m. long, from the Clarence Railway about 4 m. north-east of Stockton to Hartlepool, was made without an act of parliament, and opened in 1840; but in 1843 the company obtained an act of incorporation.

Stratford and Tamworth Junction.—See Eastern Counties and Tamworth Railways.

Sussex—See Beachy Head's Steam Coal, etc. Syon and Peterborough.—See Midland.

Taff Vale—[F. C., p. 265.].—Main line opened throughout, April 1846. In 1844 the company obtained an act for a branch of 3½ m. to Penarth Harbour (which they had purchased), which has since been completed; and for a branch of 3½ m. to Neath, which was completed in 1846. In September, 1845, they opened the greater part of the Tumble Wells branch, from near Mumford, which was made in anticipation of an act of parliamant and completed in 1846. In 1845 they obtained acts to sanction the last-mentioned branch; to enable them to alter and extend the Canterbury, Ramsgate, and Margate branch, and for the formation of two lines from Ramsgate to the Channel, in order to enable them to purchase the Canterbury and Whitstable Railway; and to widen the London and Greenwich Railway, which they propose to extend to Ramsgate; and they have also obtained acts for enlarging the station at Ashford, as a central locomotive depot; for making a railway of 2½ m. from the London and Greenwich Railway, which they propose to extend to Ramsgate, and for the formation of a branch to Ramsgate Park; for a line of 25½ m. from their Tumburidge Wells branch to join the Rye and Ashford extension of the Brighton, Lewes, and Hastings Railway near Hastings, with a running line of 6 m. towards Rye; for a branch of 1½ m. from Rye to Rye Harbour; and for authorising the purchase of the Gravesham, Dartford, and Gravesend Railway, about 15 m. from Dartford Junction.—The Brighton, Lewes, and Hastings Railway, which is amalagamed, as the South Staffordshire Railway, a branch of 8½ m. to Darenth; a branch of 32½ m. to Mote End; a branch of 29 m. to Chilham; a branch of 24½ m. to Willingham, and a branch of 12½ m.; act passed 1846. See Birmingham, Wolverhampton, and Dudley.
of less than 1 m. The gauge of the line is 4 ft. 8½ in. See Aberar

Taw Vale. [P. C. p. 265].—An amendment act passed in 1845; and in 1846 the company obtained powers for extending the line from Barnstaple Junction, and the London and Birmingham Railway at Credenhill, a distance of nearly 31 m. An arrangement for leasing the line to the Bristol and Exeter Railway Company has been completed.

Tanley, Sandfordsfoot, and South Wales. — The act, passed in 1846, is for making a railway to connect the Sandfordsfoot Rail-

Wheslade. — From Skipton to the Leeds and Thirsk Railway at Arthington, 21 m.; and two short branches, one at Skipton and one to form a second junction with the Leeds and Thirsk

[Image 0x0 to 519x820]
Railways of Scotland.

Aberdeen.—From Aberdeen to the Arbroath and Forfar line at Friockheim, 494 m.; branch to form a second junction at Guthrie, 792 m.; Forrester branch, 2 m.; Brechin branch, 34 m.; total, 55 m.; act passed 1845. To lease the Arbroath and Forfar Railway. See also Dundee.

Dundee Junction.—From Airdrie to Bathgate, nearly 141 m.; branch to Whithorn, 15 m.; Branch to Blackbank nearly 20 m.; total, 20 m. Act passed 1846, and gives power to lease or sell the line to the Edinburgh and Glasgow Railway Company.

Ayrford.—From Kintore to Alford; length nearly 16 m.; act passed 1846.

Airdrie and Forfar. [P.C. p. 265.].—An act of 1846 sanctions the leasing of the line to the Aberdeen Railway Company, in consequence of which the gauge will be widened to 4 ft. 6 in. and a station will be laid.

Arrochar (formerly Johnstone and Arrochar). [P.C. p. 265.]—Gauge originally 4 ft. 6 in., but altered to 4 ft. 8 in. The repairs to the works on the Glasgow, Paisley, and Greenock line to the Glasgow, Kilmarnoch, and Arrochar Railway Company, Ayshire and Bridge of Weir.—From the Glasgow, Paisley, and Coltness Railway, to Kilbrackan; 1 m.; total length, 5 m.; act passed 1846. Sold to the Glasgow and Ardrossan Railway Company.

Ballyconnel.—From the Paisley and Ayr Railway Company Balllochney. [P. C. p. 266.]—Gauge originally 4 ft. 6 in., but to be altered to 4 ft. 8 in., under an act of 1845. See Monkland Railway.

Caledonian.—Main line, from Carlisle to Carrawath, 720 m.; thence to Edinburgh by a branch of 274 m.; and by another branch to the Wishaw and Coltness Railway, by which is formed the Clyde and Caledonian Junction line, by which it approaches Glasgow. The original act, passed in 1845, also sanctions branches to the Scottish Central Railway and the West Country and Worcestershire and Irish Counties, and several minor junctions, making in the whole 1871 m. Under several acts of 1846, the amalgamation of the Clyde and Caledonian Junction with this Company, and the purchases of the Glasgow, Garnkirk, and Coatbridge line, are sanctioned; and the Caledonian Company are empowered to deviate their line 2 m. near Castletownshend, and to deviate 1 m. of the Clyde and Caledonian Junction line; to form short branch and terminal railways at Glasgow, amounting to about 2 m.; and to make branches amounting to 14 m. from their Casterley branch to the Glasgow, Garnkirk, and Coatbridge Railway. See also Glasgow, Barburry, and Nellston Direct; Glasgow, Kilmarnoch and Arrochar; Glasgow Southern Terminal; and Scottish Central. The company also proposes to amalgamate with the Caledonia and Dundemortonshire Junction. According to the terms of the act, which was passed in 1846, this is a railway from Glasgow to Dunbarton and Lochleven, 'with branches to Helensburgh and other places.' The length of the main line is 109 m.; of the branches, 197 m.; total, 306.

Clyde and Caledonian Junction.—From the Paisley and Govan Railway at Rutherger to Hamilton, with a branch to the Wishaw and Coltness Railway at Motherwell. Main line rather over 8 m.,Motherwell to Coatbridge, and another short branch 14 m. in the whole. Act passed 1845. Amalgamated with the Caledonian Railway, which see.

Clydesdale.—See Glasgow, Paisley, Kilmarnoch, and Ayr.

Tye-side.—From Ferryhill, near Aberdeen, to Aboyne; length, 29 m. The act, passed in 1846, confers powers for leasing the line to the Scottish Central Railway Company, whose line it joins at Dunblane.

Dundee and Arbroath. [P. C. p. 266.]—Gauge to be altered to 4 ft. 8 in. An act of 1846 authorizes a branch to Broughty Ferry Castle, and a branch to the Arbroath and Forfar line at Almerieloch. Length, under 14 m.

Dundee and Northyke. [P. C. p. 266.].—Leased to the Dundee and Edinburgh. Original gauge, 4 ft. 6 in.

Dundee and Perth.—Length, 204 m.; act passed 1845. A second act, of 1846, sanctions some deviations in the line, a short extension at Perth, and the leasing or purchase of the Dundee and Northyke Railway.

Dumfries.—To connect coal-fields with the Monkland canal. Length 1 m.; act passed 1843.

Dumfries.—Main line, to the railway station of the Edinburgh and Glasgow Railway to Bathgate, nearly 114 m.; Mid Calder branch, nearly 24 m., Binny quarries branch, 13 m.; Whithorn branch (from Barrack), nearly 54 m.; Whithorn branch (from Bathgate), nearly 3 m.; total, about 284 m.; act passed 1846. Leased to the Edinburgh and Glasgow Railway Company.

Edinburgh and Leith. [P. C. p. 266.].—Original gauge, 4 ft. 6 in. Act of 1846, and to be improved for locomotives, by the North British Railway Company.

Edinburgh and Glasgow. [P. C. p. 266.].—Opened February 1842. An act authorized on 23rd March 1841 to join Edinburgh and Glasgow, to join the North British and Edinburgh, Leith, and Grainstone Railways at the North Bridge, which extension was opened in January 1846, by an act of 1845 authorizes the leasing of nearly 64 m., consisting of the Edinburgh, Leith, and South Queenferry. Arrangements were made by the Directors for amalgamating with, purchasing, or leasing, the Monk to Kirkcaldy railway; total, 414 m. of the 464 m. of the Edinburgh, Leith, and South Queensferry, which will be laid.

Adjoining Railways.—In 1846, the company proposes to amalgamate with the Edinburgh and Northern Railway Company.

Edinburgh and Leith, and Granston (originally Edinburgh, Leith, and Newhaven). [P. C. p. 266.].—The name was changed in 1844, by an act which supplied the gap between Edinburgh and Leith, and one of 1 m. to Granston. The total length of the present line is nearly 43 m. Part of the main line was opened in 1846, and the branch was resumed to Newhaven in 1846. The company proposes to amalgamate with the Edinburgh and Northern Railway Company.

Edinburgh, Leith, and Northern.—By the original act of 1845 this is a main line of 304 m. from Berwick-on-Tweed, on the Firth of Forth, to Perth, with a branch of 34 m. to Cupar or Cupar, and one of 1 m. at Aikness to Cupar, and one of 1 m. to Perth, and one of 1 m. to Granston, and one of 1 m. to Newhaven. The company proposes to amalgamate with the Glasgow, Garnkirk, and Coatbridge Railway, which see.

Garinish and Glasgow. [P. C. p. 266.].—The original gauge of this line was 4 ft. 6 in., but, as stated there, 4 ft. 8 in.; but it was not an act for increasing the width, but an act for leasing the line to the company to be increased to that width. By an act of 1844, authorizing extensions to the amount of 427 m., it was provided that the company was changed to the Glasgow, Garnkirk, and Coatbridge Railway, which see.

General Terminus and Glasgow Harbour.—From the Police and Govan Railway to the river Clyde and the harbour of Glasgow, 1 m.; with branches to the joint line of the Glasgow, Paisley, and Greenock, and Glasgow, Paisley, Kilmarnoch, and Ayr Railways, and to the Harbour, Barburst and Helensburgh Direct line; total length, under 22 m.; act passed 1846.

Glasgow, Airdrie, and Monkland Junction.—Main line, from Glasgow to Airdrie, 101 m.; branches to the Clyde and Junction and Garvick Extension lines, and to Mile-end, 4 m.; total, 145 m.; act passed 1846. Leased to the Monkland Mineral Railways, which see.

Glasgow, Barrhead, and Nellston Direct.—From Glasgow to Croftend, 104 m.; branches at Greenock, 130 m.; branches at Greenock and Coltness to Greenock, and Kilmarnock and Ayr, and to the Glasgow, Barrhead, and Nellston Direct line; total length, under 22 m.; act passed 1846.

Glasgow and Belfast Union.—From the Glasgow, Paisley, Kilmarnoch, and Ayr line (to the owners of which it is to be made over) to the line of the Belfast and Northern Counties Railway, 4 m.; to Maybole; act passed 1846. This is only a part of a contemplated

Glasgow, Dunfries, and Carlisle.—From the Glasgow, Paisley, Kilmarnoch, and Ayr Railway, near Cannock, to the Caledonian Railway near the crossing of the river Sark, nearly 65 m.; Canock branch, 8 m.; Ainslie harbour branch, under 1 m.; Cawrick branch, 141 m.; total, 89 m. Act passed 1846. To be
amalgamated with the Glasgow, Paisley, Kilmarnock, and Ayr, and the portion from Newcraighall to Gretna to be worked by the Caledonian Railway Company.

Glasgow, Garnkirk, and Coatbridge. — This railway is the line originally called the Garnkirk and Glasgow (which see), as extended under an act of 1844 by new lines, one of which joins the Wishaw and Coltness, to the extent of 24 m. Of these the Garnkirk and Coatbridge extension, of rather more than 16 m., opened in 1845, is the first act obtained with a view to widen the gauge to 4 ft. 8 in. Under three new acts of 1846 the line is transferred, by sale, to the Caledonian Company, and an extension of 10 miles was sanctioned. The line, and the new branches mentioned under Caledonian are sanctioned.

Glasgow Junction. — From the Edinburgh and Glasgow Railway, crossing the Forth near Portobello, to Fetteresso, in Morayshire.

Glasgow, Kilmarnock, and Ardrossan. — From the Glasgow, Barrhead, and Neilston Direct Railway at Crofthead to Kilmarnock, 14 m.; Ardrossan branch, nearly 108; Irvine branch, 34 m., and some smaller branches; total length, about 349 m. Act passed 1846. The company have purchased the Ardrossan Railway and Harbour; and the line has been projected in connection with the Caledonian.

Glasgow, Paisley, and Greenock. [P. C. p. 266. — Opened throughout in March, 1841. Acts of 1846 authorize a branch of 1 1/2 m. from Greenock to the new Harbour at Port Glasgow; from Greenock to the new Harbour at Gourock.
Percy and Inverrowen Railway, (a scheme abandoned for the present during the session of 1846), to Aberfeldy; length nearly 93 m.; act passed 1846.

An Act to incorporate the shipper, and Colman, (originally called Shute and Wiltonstown).—A mineral line of about 85 m. is extension of the Wishaw and Coltness Railway; made under an act of 1841, and opened in June, 1845. An act of 1846 authorises the line, and the construction of branches from it of nearly 14 m. to Shotts, of nearly 44 m. to Climping, of 52 m. to Bathgate, and of 83 m. to join the Caledonian Railway.

Local and Colman. [P. C. p. 286.]—An act of 1846 authorises the construction of a line of nearly 23 m. from near the southern termination of the Caledon branch to Mudirudorf, with a branch from it of rather more than 6 m. to Goodickhill, in the parish of Shotts; making a total of 5 m. An agreement had been made for the sale of the whole undertaking to the Edinburgh and Glasgow Railway Company; but it is now (November, 1846) expected that a union with the Caledonian Railway will be substituted for the intended amalgamation.

RAILWAYS OF IRELAND.*

Belfast and Ballymena.—Main line nearly 38 m.; Carrickfergus branch 3 m.; Sandilands branch 2 m.; total 38 m.; act passed 1845.

Belfast and Carnew. [P. C. p. 286.]—An act of 1845, 30 m. of the line was to be from Belfast to Downpatrick, 24 m.; with branches to Holywood, Newtownards, Bangor, and Donaghadee, amounting to 30 m.; total length, 65 m.; act passed 1845.

Clonmel and Thurlow.—From the Waterford and Limerick Railway at Clonmel, to the Great Southern and Western Railway at Clonmel, by a branch to the Severn Collieries, 104 m.; total length, 184 m. Act passed 1846. Sold to the Great Southern and Western Railway Company.

Cork and Portarlington. Main line, 60 m.; act passed 1845.

Cork, Blackrock, and Passage.—From Cork, through Blackrock, to Passage West; length, 66 m.; act passed 1846.

Cork and Waterford.—Main line, 78 m.; branch to Fermoy, 18 m.; a branch to Tramore, 1 m.; total length, 97 m.; act passed 1846.

Dalkey.—See Dublin and Kinsgstown.

Dundalk and Collon Line Junction.—Main line from Armagh to Portrush, 70 m.; branch to Dundalk, 13 m.; branch to Ballymoney, 41 m.; total length, 121 m.; act passed 1846.

Dublin and Belfast Junction.—Main line, from Drogheda to Portadown, 56 m.; branch to Navan, 17 m.; act passed 1845. An agreement was made in 1846, for selling the Navan branch to the Dublin and Drogheda Railway Company.

Dublin and Drogheda. [P. C. p. 286.]—Open May, 1844; gauge 5 ft. 3 in. An act of 1845 authorises the Howth Branch, 33 m. long, the greater part of which was opened in July, 1846. The company has purchased the joint branch of the Dublin and Belfast Junction, which see.

Dublin, Dundrum, and Rathdrum.—Dublin to Dundrum, ranging by Kilbride, to Rathburnham, over 21 m.; total length, nearly 53 m.; act passed 1846.

Dublin and Kingsbridge.—[P. C. p. 286.]—An extension of 18 m. to join the Great Southern line was made without the sanction of act of parliament, and opened in March, 1844. It follows the line of a tramroad made by the Commissioners of Kingsbridge, which was authorised by an act of 1846, and extends from Millmount to the bridge of Ballyclogh. See Waterford, Wexford, Wicklow, and Dublin.

Dundalk and Enniskillen.—From Dundalk to the Newry, and Enniskillen line at Clones, 403 m.; the remaining distance, about 36 m. from Clones to Enniskillen, to be made by the Newry Company, with provisions for its joint use by both lines; act passed 1845.

Dundalk Western. [P. C. p. 286.]—Abandoned.

Dundalk and Kingsbridge.—See Kingsbridge and Great Southern and Western.

Great Leinster and Munster.—Owing to financial condition, and the increase of 1841, was never carried into effect. The Great Southern and Western line has superseded the Great Leinster and Munster between Dublin and Cabra, and the company was winded by one of the provisions of 1841 from Kilkeny to Clonmel. The Wexford, Caslou, and Dublin Junction line is to be amalgamated with this undertaking under the new name of the Irish South-Eastern Railway.

Great Southern and Western.—Main line from Dublin to Cashel, 984 m.; branch from Monasterevin to Carlow, 54. For these the act in 1846 was passed in 1846. A second act in 1846 sanctioned an extension of 77 m. to Cork, with a branch of 41½ m. to Limerick.

The gauge of all Irish railways is required to be 5 feet 3 inches, in accordance with a recommendation made by the Board of Trade in 1842.

* The gauge of all Irish railways is required to be 5 feet 3 inches, in accordance with a recommendation made by the Board of Trade in 1842.

rick. The Limerick branch, however, being identical with part of the Waterford and Limerick Railway is not to be made if that line is carried into effect. Another act passed in 1846, sanctioned the extension of nearly 1 m. to the river Lee at Cork. Of the original route the portion between Dublin and Cashel, about 564 m. was opened in August, 1846. See also Cork and Clonmel; Limerick, Ennis, and Killaloe Junction; Milford and Foreway; Waterford and Limerick, Kilkenny, and Waterford; this last, which see.

W. Return.—From Kilkenny to the Great Southern and Western Railway near Cuddagh; length 36 m.; act passed 1846. Part of a much more extensive scheme called the Waterford and Limerick Railway. Power given to lease or sell the line to the Waterford and Kilkenny Railway Company. Kilcreggan Junction.—From Mallow to Killkenny, length 283 m.; act passed 1845.

Limerick, Ennis, and Killaloe Junction. Main line, from Limerick to Ennis, 264 m.; branch from Limerick to Killaloe, Waterford and Limerick, and Ennis. Dublin, and Killaloe Junction with Great Southern and Western, 3 m.; total length, about 37 m.; act passed 1846. Power given to lease or sell the line to the Great Southern and Western Railway Company. Kilcreggan Junction.—From Mallow to Kilkenny, length 283 m.; act passed 1845.

Limerick, Ennis, and Killaloe Junction. Main line, from Limerick to Ennis, 264 m.; branch from Limerick to Killaloe, Waterford and Limerick, and Ennis. Dublin, and Killaloe Junction with Great Southern and Western, 3 m.; total length, about 37 m.; act passed 1846. Power given to lease or sell the line to the Great Southern and Western Railway Company. Kilcreggan Junction.—From Mallow to Kilkenny, length 283 m.; act passed 1845.

Limerick, Ennis, and Killaloe Junction. Main line, from Limerick to Ennis, 264 m.; branch from Limerick to Killaloe, Waterford and Limerick, and Ennis. Dublin, and Killaloe Junction with Great Southern and Western, 3 m.; total length, about 37 m.; act passed 1846. Power given to lease or sell the line to the Great Southern and Western Railway Company. Kilcreggan Junction.—From Mallow to Kilkenny, length 283 m.; act passed 1845.
or their situations on his instrument, names wholly different from those in the copy placed before him. To accomplish this he has to suppose a change of clef, or clefs, and thus give new designations to all the lines and spaces. For instance—and without going into the extreme case of transposing from a score—a pianoforte player is required to transpose an air a whole tone lower, from A to G. For this purpose he must assume a change of keys, and, the transposition made, the tenor, and each note to be played an octave higher than it is written; the base into the alto, and each note to be played an octave lower than it is written. Example in A.

The same as read by the performer, when transposed to G.

The difficulty attending this process is so great, that no amateur, and few discreet musicians, unless professed accom­panists, or well acquainted with the composition to be trans­posed, will undertake the task; for to perform it in an artist­like manner, at first sight, requires a degree of practical skill only to be gained at the expense of much time that might be employed to far greater advantage in studying those higher branches of the art in which the most experienced will always find something to learn. Our remarks, it will be understood, relate to performers on the pianoforte and organ. To those who read from a single staff, and play single notes only, as violaists, flautists, &c., the task of transposing is comparatively easy.

To meet all the demands of Transposition, a familiar knowl­edge of no less than seven clefs is necessary, and two of these—the mezzo-soprano, and baritone, or bass clef on the 3rd line [Clef, F. C.]—may be said to have become obso­lete, for we venture to assert that not one musician in five hundred is practically acquainted with either.

The annexed table will exemplify the use of clefs in transposi­tion. It shows how to transpose a given key-note—A for instance—into any other note of the scale, and, conse­quently, how to transpose the whole of any composition. It is hardly necessary to add, that the semitone scale, as con­cerns line and space, is governed by the diatonic; that A, A♭, &c., have the same places in the staff as the natural notes represented by the same letters.

TRAVERS, JOHN. The author of compositions so popu­lar, elegant, and charming as 'Haste, my Nanette,'—'I, my dear, was born to-day,'—'When Bibo thought fit,'—'Soft Cupid,'—is fairly entitled to a few lines in our biographical department, though his life was void of any remarkable inci­dent. He was educated first in St. George's Chapel, Winds­or, afterwards under the celebrated Dr. Greene [GREENE, P. C.]. About the year 1725 he followed Kelway as or­ganist of St. Paul's, Covent Garden, and subsequently filled the same situation also at Fulham. In 1737 he was appointed organist to the Chapels Royal. He died in 1758, and was succeeded in the latter office by Dr. Boyce.

Travers composed much cathedral music, but except an anthem, 'Ascribe unto the Lord,' and a 'Te Deum,' his produc­tions for the church have fallen into disuse. We will

TRAVERSE. (PERSANDE, P. C.)

TRENASON. [Law, CRIMINAL, P. C.S.]

TRENTON. Antonio de Ridolfi, 1768, few necessary, the Chelouidm

TREVIGI, or TREVISO, GIROLAMO DA, born at Trevigl in 1508, was apparently the son of the painter Pier­maria Pennacchi, who was doubtless his son's instructor in the art. Girolamo, however, not wholly satisfied with the accuracy of the Venetian painters, became an imitator of the style of Raphael, and combined to a considerable extent the qualities of both schools. He lived some time in Bologna, where he painted some excellent works, especially from the story of St. Antonino of Padua, in oil, in the cathedral. He left Bologna in consequence of the superior fame of Pietro­ da Vaga, then at Bologna. After painting several works in Venice, Trent, and some other places, he came to England and entered the service of Henry VIII, who em­ployed him as architect and engineer, with a fixed salary of nearly 100l. per annum. He was engaged in the capacity of engineer in the year 1544 before Boulogne, and was there killed by a cannon-shot, in his 36th year.

There are some fine portrait paintings of Girolamo; they are well coloured and in an elaborate but broad manner, much in the style of the portraits by Raphael; there is a fine specimen in the Colonna palace at Rome; it is a half-length of a man in the pictureque costume of the period, and is probably a signature in his hand. There are or were other pictures by Girolamo in this palace. A picture of the Madonna with various saints, which, according to Guicciardini, was Girolamo's masterpiece, is now in the collection of Mr. Solly, in London: it was for­merly in the church of San Domenico at Bologna.

There was an earlier painter called Girolamo da Trevigl by whom there are still works bearing dates from 1470 to 1540; his surname according to Federici was Aviano.

(Vasari, Vite de' Pittori, &c.; Bartich, Figuren-Graevur; Neumann, Algebrograevur, Lexicon.)

TRIESTOSTERNON, a genus of fossil amber from Tigliate forest. (Owen.)

TREVIGL, or TREVISO, GIROLAMO DA, born at Trevigl in 1508, was apparently the son of the painter Pier­maria Pennacchi, who was doubtless his son's instructor in the art. Girolamo, however, not wholly satisfied with the accuracy of the Venetian painters, became an imitator of the style of Raphael, and combined to a considerable extent the qualities of both schools. He lived some time in Bologna, where he painted some excellent works, especially from the story of St. Antonino of Padua, in oil, in the cathedral. (Vasari, Vite de' Pittori, &c.; Bartich, Figuren-Graevur; Neumann, Algebrograevur, Lexicon.)

TRICARPELITES, a genus of fossil fruits from Sheppe­ry. (Bowerbank.)

TRICHOMANES, a genus of ferns belonging to the sub-order Hymenophylaceae. The theece are on an elongated rhizome receptacle within a cup-shaped involucre of the same texture with the frond.

T. speciosum is the only British species. It is extremely rare, and very beautiful, combining the characters of the true ferns, mosses, and sea weeds. In texture as well as in color it resembles some of the marine algae, and it is found to assume the same life-like appearance when immersed in water after being kept perfectly dry for many years. It is found at Kil­larney, Wicklow, and on the beach at Inch in Ireland.

The soil which seems to suit it best is a mixture of loam and sand, interspersed with pieces of turf.

(NEWMAN, British Ferns; BAILING, Manual of British Botany.)

TRICHONEMA, a genus of plants belonging to the

TRICHTON, or TRICHTON, TERRA, 1560, S. and F. C., an

TRICHROMIC, or TRICHROMIC, TERRA, 1560, S. and F. C., an
TRIANGLES, a genus of plants belonging to the natural order Primulaceae. It has a 7-parted calyx, a rotate 7-parted corolla, and 7 stamens inserted at the base of the corolla. The capsule is many-seeded, opening with a revolute falcate valves. The seeds are invested with a reticulately tunic. T. europaeus has oblong oblong obvolute obwisp, a stem from 4 to 6 inches high, with the leaves mostly at the top. The flowers are on short peduncles, white, with a yellow ring. The valves of the capsule soon fall off. It is native of England and the Highlands of Scotland. (Babington, Manual.)

TRIGLA, a genus of Acanthopterygious osseous fishes, popularly known as Gurnards, and belonging to the family Serranidae in the arrangement of Cuvier. The head of Triogla is broad and angular: the opercle and subopercle are armed with spines; the body is scaly: there are two distinct dorsal fins; beneath the pectorals are three detached rays; the branchiostegous membrane has seven rays; both jaws and the front of the vomer are armed with sharp teeth. The gills are separate, the gill-covers are concave, the gill membranes are united behind the branchiostegous membrane. The head, trunk, and pectoral rays are covered with a thick, silvery, and often glossy coat.

United States of North America, 688

UDAL TENURE. [Shetlands, P.C., p. 365.]

Ulodendron, one generic division of the great group of Lepidodendroid families of plants which occur in the coal formations.

UNDULATORY THEORY OF LIGHT. This subject has been already treated briefly, under the same designation; and for further notices concerning its principles, as well as for its applications explanatory of the remarkable phenomena of light, the reader is referred to Diffraction, and to Polarization of Light (P.C.), also to the following articles, which have been introduced in this Supplement: Circular Polarization; Colours of Planets; Elliptical Polarization; Polarized Movements; Polarized Rings; Swiftest Propagation, Principle of; and Vibrations of Light.

UNION OF ESTATES. [Merger, P.C.]

UNITED STATES OF NORTH AMERICA. Since the article Oregon Question, P.C.S., was written the dispute concerning the Oregon territory has been settled. On the 29th of June, 1846, Sir Robert Peel, in the speech in which he announced his resignation of office, informed the House of Commons that the British government had offered a convention to the government of the United States, of which the President of the United States, on the 13th of June, 1846, announced the acceptance by the American government, without the addition or alteration of a single word. The first proposal of the British government was as follows:

"That from the point in the 49th parallel of N. Lat. in which the boundary laid down by existing treaties between Great Britain and the United States terminates, the line of boundary between the territories of the two countries shall be continued westward along the 49th parallel to the middle of the channel which separates the continent from Vancouver's Island, and thence southerly through the middle of the said channel and the Fossa Straits to the Pacific Ocean. Provided the navigation of the channel and straits, south of the 49th parallel, shall be free and open to both parties."

This leaves to the British the whole of Vancouver's Island, with equal rights of navigation in the Straits. The second proposal was:

"That from the point at which the 49th parallel of N. Lat. intersects the great northern branch of the Columbia river, the navigation of the said branch shall be free and open to the Hudson's Bay Company, and for all British subjects trading with the same, to the point where the said branch meets the main stream of the Columbia, and thence down the main main stream to the seashore, with free access into and through the said river or rivers; all the usual portages along the line thus described to be free and open to both parties. Provided that in navigating the said river British subjects shall be on the same footing as those of the United States: it being always understood however, that nothing herein shall be considered as preventing the government of the United States from making any regulations as to the navigation of the river not inconsistent with the present convention."

The circumstances under which Texas has been annexed to the Union are stated under Texas, P.C.S.

Michigan, described as a territory in P.C., was admitted into the Union as a State at the end of 1835. The Governor is elected for two years, and his salary is fixed at present at 1500 dollars per annum. The Senate consists of 18 members, elected for six years; the House of Representatives of 53 members, elected annually. The pay of the members is three dollars a day during the session. The seat of government is at Detroit, or wherever the legislature shall direct, till 1847, when it is to be established permanently. The legal establishments are a Court of Chancery, a Supreme Court, Circuit Courts, and a District Criminal Court. The Chanceller has a salary of 1500 dollars, and there are five Chancery Circuits. In the Supreme Court there is a Chief Justice, with a salary of 1600 dollars, and three associate Judges with salaries of 1500 dollars each. The four Judges of this court are appointed by the Governor, with the advice and consent of the Senate, for a period of seven years. There are four judicial circuits, in each of which one of the Judges of the Supreme Court presides. The University of Michigan, which was opened at the end of 1832, has since been gradually increasing. At the end of 1846 the main institution at Ann Arbor had about 70 students, and the five branches, or preparatory schools, at Tecumseh, Romeo, Kalamazoo, White Pines, and Ann Arbor, about 180 students. The professorships were—1, Greek and Roman Language; 2, Mathematics; 3, Moral and Mental Philosophy; 4, Geology and Mineralogy; 5, Botany and Geology. In 1844 the number of scholars in the Common Schools was 66,016, and the amount appropriated from the state treasury among the several districts was 28,963 dollars. Michigan is thought, both as to the means of education and the success of the system pursued, to be little behind the most forward of the eastern States. The state prison at Jackson is constructed on the Auburn plan. The Central Railroad runs from Detroit to Marshall, 110 miles, and 36 miles more of the road were expected to be completed by the end of 1846. The Southern Railroad runs from Monroe to Hillsdale, 68 miles. The population of Michigan in 1830 was 31,639; in 1840 it was 212,307. There are no slaves.

Florida was admitted into the Union as a State in 1845, the first Governor having entered upon his office in October of that year. The Governor is elected for four years, the Senators for two years, the Representatives for one year. The number of Representatives is never to exceed 60. The Judges of the Supreme Court are to be elected by a concurrent vote of both Houses, at first for five years, and after that according to good behaviour. The right of voting is to belong to every free white male, aged 21 or upwards, who has resided in Florida two years, and six months in the county in which he votes, and who shall be enrolled in the militia or by law be exempt from service therein. No laws are to be passed to emancipate slaves, or to prohibit the importation of persons for the use of slaves with them. The General Assembly may prevent free coloured persons from entering the State. The population in 1830 was 54,750; in 1840 it was 54,447, of whom 29,717 were slaves. (American Almanac, 1837, 1845, 1846.)

Uranoscope, a genus of Acanthopygeous oceanic fishes of the perch family, and very nearly related to the weavers (Tachinina) of the British seas. One or two species inhabit the Mediterranean. The head is nearly cubical, and the eyes placed in the flat summit, so that they look upwards; hence the name. The mouth is turned up in a similar manner. This arrangement agrees with the habits of the fish, which lives itself in sand all but the summit of the head, and thus lies in wait for its prey. Its colour resembles the sand in which it lives.
V.

VACHELLIA, a genus of plants belonging to the natural order of Leguminosae, is divided into five species, the 5-toothed; the corolla tubular, gamopetalous, and 5-toothed. The stamens are numerous and distinct; the legume cylindrical and turgid, scarcely dehiscent, filled with pulp, and a dozen or more seeds. 5. *Farnesiana* is a native of the East and West Indies and Africa. It is a large shrub or small tree, with straight thorns. The leaves are bipinnate, the leaflets linear and nearly flat; the peduncles and petioles more or less hairy; the flowers capitate, the heads globular, 2 or 3 together, each on an axillary peduncle. The bark exhibits a considerable quantity of gum. The flowers when distilled yield a delicious perfume.

(Lindley, *Flora Medica*.)

VAILLANT, WALLERANT, a very distinguished portrait painter, was born at Lille in 1625, and was the pupil of Erasmus Quellius, at Antwerp. He painted the portrait of the Emperor Leopold I. at Frankfort, and many of the people of his court. He subsequently went with Marshal Grammont to Paris, and was there equally distinguished by the French court. After having amassed considerable riches he died at Amsterdam, in 1677.

Vaillant was employed in 1656 at Brussels by Prince Rupert to assist him in executing some plates in the new method of measuring time then communicated to him by Siegen (Siegen, Ludwig von, P. C. S.) As Vaillant is the first artist who engraved in this style, his prints have more than ordinary interest. Among these are two portraits of Prince Rupert, one of which is inscribed—Print Robert, of van de Swarte Prent Konst, which is one of the principal causes of Siegen's being so long deprived of the merit of his invention.

Vaillant had four younger brothers, who were all painters or engravers and his pupils.

(Desenfans, *Vies des Peintres Flamands, etc.; De Lalive, *Histoire de la Gravure en Matiere Noire*.)

VALENS, AURNHANUS, a Roman jurist, whose age is partly determined by the fact that he cites Juvencus and Julius (Dig. 4, tit. 4, s. 33), from which we may conclude that he was younger than both. He is called Aurnanus in the Florentine Pandect. He was a Sabinius, as appears by his being placed by Pomponius among the followers of Juvencus. It appears that he was living under Antoninus Pius (Capitol., Pont. 19), and except the text, as Carolo gives, he is called Salvius Valens. His complete name may have been Salvius Aurnanus Valens; or Salvius in this passage may be separated from Valens and mean Salvius Julius. But there is a rescript of Pius (Dig. 49, tit. 2, s. 7, § 2) addressed to Salvius Valens.

Valens wrote seven books on Fideiconcimmissa, from which there are excerpts in the Digest; and there is also in the Digest a passage from the seventh book of a work on Antics. Valens is mentioned by Pomponius, and cited several times by Paulus (Dig. 4, tit. 4, s. 33).

VALABOR. [TAVASOR, P. C.]

VAN, or WAN. [TAVLASSOR, P. C., p. 360.]

VAN HOECK, JAN, a distinguished Flemish painter was born at Antwerp about 1600. He first studied for one of the learned professions, but became the pupil of Rubens, and studied afterwards some time in Rome. While in Italy he was invited by the Emperor Ferdinand II. to his court, and was much employed by him. He eventually returned to his own country, where he died, according to Houbraken, in 1652.

Van Hoock was admirable in history and portrait, and excelled both in light and shade and colour; his figures also are better drawn than is the case with those of the pupils of Rubens. He made several copies of the "Christ in the Cross" in the church of Saint-Sauveur, or the cathedral, at Bruges, one of the finest pictures in Belgium. The Christ, which is of the size of life, has extraordinary effect and remarkably superior to the celebrated Christ of the church of St. Michael, at Ghent, by Van Dyck, and it is more real and impressive than any of those of Rubens: beneath the cross are the Virgin and other saints. There is a print of it by the younger Cornelius Galle; this engraver however is not very accurate in his drawings. In the middle of the Christ, the composition of the picture is meager and formal, and wants dramatic truth.

VARIATION OF PARAMETERS. A parameter was at one time given a particular conic section; being the third proportional to a diameter and its conjugate. In time the word was applied to any line which serves by its value to distinguish, or to help to distinguish, one individual of a family of curves from another; thus the radius of a circle, the axis of an ellipse, the co-ordinates of the centre of either, were called parameters. When a word gets into the descriptive name of a method, it may happen, as part of a phrase, to outlive its own separate use: and such has been the case with the word parameter. As this word is now generally abandoned, and element is the most frequent substitute for it, it would be desirable to speak of variation of elements.

Whatever phrase we may use, the thing occurs both in physics and mathematics, in modes which are closely connected with each other. A planet moves in a curve which is not an ellipse, but which would change and become an ellipse if the disturbing attractions of the other planets were removed, and that of the sun only continued. The easiest way of calculating the planetary motions is to consider the planet as moving in this ellipse, while during the motion the elements which determine the ellipse are perpetually changing; so that the form and position of the ellipse both vary. This is done in such manner that the ellipse of each moment is that which the planet would go on to move with at that moment, if the disturbing attractions were all removed. The advantage is that in this case the elements will vary very slowly, or it will be long before the disturbing attractions produce much effect. In theory, any curve might be taken. A plane of first importance might be supposed to move in a parabola, which varies its distances and position in a manner to be determined. In *Tropocodals of Curves, P. C.*, all the curves given are produced by a point moving in a circle with variable elements; that is, of variable centre, though given radius. If it were required to investigate trochoidal curves with loops and undulations of different magnitudes, the best way would be to consider them as made in the same manner, with a circle of variable radius also: or else to make both circles variable.

In the differential calculus the variation of elements is investigated. If an algebraical expression containing some variables and some constant elements be proper to answer a certain purpose, it is not impossible that it may answer the same purpose when the elements are made variable, provided they are made to be variables in a proper manner. Now, if the purpose which is to be answered involves differentiation, the infinity of the number of suppositions which may be made as to the variation of the (former) constants is equivalent to introducing an arbitrary function instead of each constant, to be determined by the conditions of the question. Two species of cases have frequently arisen.

1. When under certain circumstances a problem is solved by an expression containing certain constants, and the circumstances are then altered; it is often convenient to inquire whether the altered problem might not be solved by the same expression, on the supposition that the constants become variable. And the question then is, how the (former) constants are to be made to vary.

2. Without any alteration of the circumstances, having a solution which contains constants, it may be asked how to substitute different variables in place of constants, so that the altered expression may still be a solution.

In both cases it is obvious that as soon as the constants are made variable the differential co-efficients of all expressions into which they enter, and into which these co-efficients enter, alter; and it is necessary to discover what they had before. These new terms, which we may describe as functions of the variations of the elements, must, in the first case above noted, be so taken as to provide for the effect of the alteration, and in the second case, for the effect of the alteration, and also to provide for the effect of the alteration of the altered elements. If the constants they must destroy one another's effects altogether. We shall take a few instances in which the variation of elements is successful or unsuccessful.

P. C. Sc., No. 17.
The equation \( y' + Py = 0 \), \( P \) being a function of \( x \), is solved by

\[
y = Ce^{-Py}
\]

\( C \) being a constant. Now alter the equation into \( y' + Py = Q \) and to meet the alteration, let \( C \) become a function of \( x \). On this supposition \( y' + Py \) becomes

\[
-C'R + Ce^{-Py} + C' = 0
\]

But this ought to be \( Q \); therefore we must have

\[
-C'R = Ce^{-Py} + Q + E
\]

\( E \) being another constant. Here \( y' + Py = Q \) is solved by \( y' + Py = 0 \) and subsequent variation of an element.

Now try \( y' + Py = 0 \) and \( y' + Py = Q \) in the same manner. The first is solved by \( y = e^{x + C} \) and if \( C \) be made variable, and \( y \) thus altered be introduced into the second, it is found, making \( x = C + x \), to require the solution of

\[
x^2 + Qx^2 + 1 = 0
\]

as difficult an equation as the original. In this case then we are unsuccessful.

2. Let \( \frac{du}{dx} + \alpha x = a \). One solution of this is \( u = \frac{1}{2} x^2 + \alpha x + b \), \( a \) and \( b \) being constants. To find a more general solution of this same equation let \( b \) be a function of \( a \\ a \) being a function of \( x \) and \( y \). We have then

\[
\frac{du}{dx} = x + a + \frac{d}{dx}(x + b)\frac{da}{dx}
\]

It is to be remarked that we found them, or that we can solve this equation, if \( a \) is fixed and \( b \) is variable, and the equation will obviously still be satisfied if \( a \) and \( b \) are related so that

\[
x + y + \frac{db}{dx} = 0
\]

Now as \( b \) is what function of \( a \) we please, so also is \( db \). Hence it follows that if \( b = \phi(a) \), and \( x - y = \psi(a) \), we may make \( a \) what function of \( x - y \), we please. Let \( x = \psi(a) \), and let \( y = -\psi(a) \).

We have then

\[
\frac{u}{2} = \frac{1}{2}(x + b)(\psi(a) + b) + b = a
\]

\( \phi \) meaning any function whatever.

This subject has many developments. We have introduced it here under the idea that some students of the differential calculus may be led to consider it at an earlier period of their reading that hooks will give to them. It is to be remarked that this method does not merely search for solutions of a question: if the number of constants be sufficient, it goes direct to the most general solution. In our first example, this is the function of \( x \), but what is capable of being represented by \( C'e^{-Py} \)? In our third there is no function of \( x \) and \( y \) but what is capable of being represented even by \( y^2 + a(x - y) + b \) and also by

\[
1\left(1 + \frac{a}{x^2} + \frac{b}{x} \right)
\]

\( x \) or \( x \) and \( y \), will solve these equations, is sure to be found, if the method is successful. This point would need a little more development than we have here space to give.

**VEGETABLE MORPHOLOGY, or METAMORPHOsis.**

This department of science which contemplates the laws which regulate the forms of plants and of their particular parts. In the earlier period of the history of botany plants were studied as individuals or groups of individuals, without any reference to the general laws which govern either the external or the internal forms of plants, or those which influence the production of various forms in the same individual at different periods of its existence, or of the same species under unlike circumstances.

Linnaeus, although he never made any practical application of his idea, seems to have been the first to have suspected that the varied forms of the flowering organs, and even other appendages of the higher plants, were modifications of the leaf. In his 'Philosophia Botanica' he has the following remarkable passage:—'The origin of the flowers and the leaves is the same; the origin of the buds and the leaves is the same: the bud consists of the rudiments of the leaves; the flower comes from the rudiments of the leaves united.'

Although Linnaeus was one of the first to enunciate the laws of morphology, yet even in his time published scientific works on the subject were not numerous. The whole story of the development of the flower and of the leaf was thus apospherically proclaimed by the great Swede, and many facts pointed out by him to prove its truth, yet little or no notice was taken of this department of science by his followers. The next great names in the subject were W. H. Goethe, who at a very early age, in 1780, published a work on the vegetable philosophy of morphology, which was then the secret of the generation and organization of plants, and that it is the simplest thing that can be imagined. It was some years after that he first published his poem on the metamorphosis of the vegetable kingdom, which is the main subject of this part of the book. It consisted of three parts, and was dedicated to the memory of the great Swedish botanist Linnaeus.

This was followed by a paper on the subject, in which he clearly points out the importance of this idea of the unfolding of a primitive type. At the time these papers were published they were regarded as the fancies of a poet rather than the sober realities of scientific science. In Great Britain they found little favour, but were quietly thought over by Robert Brown, who, by a series of accurate observations, demonstrated the practical signification of the morphological idea in the arrangement of the various families of plants. The idea of Goethe was adopted by De Candolle, in his doctrine of a primitive type among plants, from which all departed by the decrease, increase, and adhesion of their organs. In this way the doctrine of morphology has more or less influenced the greatest botanical observers of the present day, and it assumes a position of the first importance in botanical inquiries.

Morphology may be divided into two great divisions. First, that which treats of the forms of plants and their organs in general, and which is only concerned with a few of those general forms which are found common to all plants; and secondly, that which treats of the forms of the various series of plants and of individual organs. This latter department is by far the most extensive and is that which contributes so greatly to the just apprehension of the relations which exist between the various groups of plants and their organs. It may be divided into two parts, one of which regards the external form of the plant, as resulting from the combination of the various tissues into organs; the others treat of the internal form which the various tissues of the plant assume.

There are certain general principles in morphology which have been expressed by the author of the descriptive characters and the systematic arrangement of plants, for example Cyclopedia, and many Cyclopedia, which has an ascending and descending axis; the former of which is the stem (Exogenes, P. C.); and the latter is the root (Root, P. C.). These may be traced downward through the various series of plants downwards till we arrive at a point where the cells exhibit no tendency to either an ascending or descending growth, as in the cells of Protozoa; or upwards till the increasing development of the stem exists in the most complicated organs. It is in the latter or higher groups of plants that the laws of morphology have been studied with greatest attention, and have led to the belief that its only application existed in the series of changes which the leaf of the higher plants undergoes in its conversion into the parts of the flower and the fruit. It is from this department of botany that the most convincing illustrations of the truth of the laws of morphology may be drawn, and it is here that the most obvious practical applications of them may be made; but form does not more distinguish the higher than the lower plants, and in many of the phenomena of the latter, general laws as general may be applied as to the highest plants.

The leaf however affords the best illustration of the nature of morphological laws. This organ may be regarded as a determinate point of departure from which the others are formed, and from which they are...
supposed to have departed. In support of this theory we have the fact, that all the organs of the axis may be traced by insensible gradation either to or from the leaf. Thus the bract is often undistinguishable from the leaf, the sepal from the bract, the carpel from the petal, the carpel from the petals, the carpels from leaves, and the ovules from kel-kulbs.

This is the series of gradations which prove the positions of morphology. When these gradations take place, as they usually do, between the different organs of the flower, it is called an ascending metamorphosis; when it takes place from the central organs of the flower to the leaf, it is called a descending metamorphosis. This latter phenomenon has, in the vegetable kingdom, given rise to objects called monsters. Most of the double flowers of our gardens are the result of a descending metamorphosis, in which petals are developed instead of stamens. As an instance of organs which have not assumed the development of leaves, but which yet are formed on the same type and obey the same laws, we may name the stipules and scales of leaf-buds.

The result of these facts is that we may regard the flower as a collection of leaves arranged in whorls, and fact a branch with a short axis. This idea explains at once those apparently anomalous occurrences where branches grow out of the fruit of the pear or the apple. The apple does not represent the growing point of a branch, which, if the circumstances no longer exist which produced the peculiar leaves from which it is formed, will take on the ordinary growth of a branch. The admission of these principles has led to the examination of each separate organ of the flower and fruits of plants, and being applied to their peculiarities, are the best means of securing a natural classification.

It is apparent that the number of leaves must normally alternate with that which preceded it. 2. That the number of parts in every series must be equal to or a multiple of the number of parts in the first or outer series. The actual departures from this theoretical structure are numerous, but they may be reduced to the simple conditions of the increase, decrease, or alteration of the various organs, which also obey definite laws.

(Vegetation in Change. Introduction to Botany, 2nd edition; Goethe, Metamorphosen der Pflanzen; Linnaeus, Philosophia Botanica; De Candolle, Théorie Elémentaire de Botanique; Schiede, Grundzüge der Wissenschaftlichen Botanik.)

VELLA (Latinised from Velecro, the Celtic name of the grass), a genus of plants belonging to the natural order Crucifera. It has an ovate pouch, with a dilated winged leafy flat style, longer than the corolla valves. The flowers are yellow, and are, as well as the pod, erect.

V. annua was found in the time of Ray on Salisbury plain, but has since been noticed. It has doubly pinnatifid leaves, and sessile flower on peduncles. V. pseudocynus, False Cyprian, or Cress-Rocket, is a native of Spain; it has yellow petals with long dark purple claws; the larger stamens are connate by pairs; the seeds two in each capsule.

This shrub, though generally kept in a greenhouse, is sufficiently hardy to live during the winter in the border in a warm aspect. Young cuttings will strike root in sand under a bell-glass.

(Don, Gardener's Dictionary; Babington, Manual of British Botany.)

VENÈRE INSPICIENDI, WRIT DE. When a woman is suspected to feign herself with child in order to produce a supposititious heir to the estate, the heir presumptive may have a writ de venire inspiciendo, to examine whether she be with child or not; and, if she be, to keep her under parental restraint. The suit is entirely conformable to the practice of the civil law: but if the widow, upon due examination, found not to be pregnant, the presumptive heir shall be admitted to the inheritance, though he hath to lose his suit, on which account, it is said, he may go about the这条s from the death of a husband (Blackstone, Comm. 1. 456).

The Roman practice is explained in the Title of the Digest (25 tit. 4): De inspiciendo venire custodiendique partu.

This title of the Digest is the most rankling of the law, in a case in which a wife denied her pregnancy and the husband maintained it. The wife had separated from the husband, and probably wished to keep the child that might be born, though by law it had not the right of inheritance. The husband alleged that she was left pregnant by her deceased husband, it was her duty to announce the fact to those whom it concerned, and to inform them that they might, if they pleased, send women to inspect her (quia venitum inspiciens). All the proceedings of inspection and of watching the woman, if she should be reported to be with child, are minutely described in the Praecox's Edict. The penalty in case of the woman not complying, with the Edict, was that the Praetor would refuse to the child the Bonorum Posemiss.

The form of the English writ De Venire Inspectando is given (Co. Litt. 6 b.), it is directed to the sheriff, and compels him to cause the woman to be examined, and to cause her to be inspected. If they find that she is with child, another writ issues, which commands that she shall be safely kept and duly inspected by the women, who must be present at the delivery. Brenton is the writer by whom this work is first mentioned.

The use of this writ is an instance in which what is called a proceeding at common law is taken from the Roman system. The writ is not obsolete, as some people suppose: it has issued within the last few years. (Co. Litt. 8 b., and N. 44 in Butler's edition; Comyns, Digest, Bastard, C.)

VENÉRIL, PIETRO MARTIRE, born at Florence in 1500, studied for the church, and entered early the Order of the Regular Canons of St. Augustine; in which he became distinguished for his learning, and rose to offices of trust. Being at Naples he became acquainted with a Spaniard, who had become a convert to the doctrines of the Reformation. Vernigili adopted some of those tenets, but concealed them for a time. Being sent by his superiors to the University of Lucca, as prior of monks, he there published a new doctrine, and was soon after compelled to fly to Switzerland, in 1542. He thence went to Strasbourg, where he was appointed Bishop of Strasbourg. In 1547, at the invitation of Bishop Cranmer, he repaired to England, where he was graciously received by King Edward VI. and was appointed Lecturer upon the Holy Scriptures at Oxford, where he met with much opposition from the heads of colleges and the higher graduates, and ran some personal risk. In 1553, after the accession of Queen Mary, being obliged to leave England, he returned to Strasbourg, where he resumed his chair as Professor of Philosophy. In 1556 he was invited by the senate of Zurich to fill the chair of theology in that University, which he accepted. In 1561 he repaired, with other Protestant divines, to the conference of Poissy, in France. In the following year Vernigili died at Zurich, much regretted. He wrote on dogmatic and ethical subjects, commentaries on parts of the Scripture, besides numerous epistles to 'His Brethren of the Protestant church of Lucca,' to the Protestant churches in Poland, to the English church, to Calvin, Bullinger, Beza, Melancthon, and other reformers, to Queen Elizabeth, and to several English prelates and noblemen. Trutboch, and Vincent, the Catholic prelates, were free from the arrogance and virulence of Luther and other Reformers, that he was deeply acquainted with the Scriptures and the fathers, and was one of the most learned writers of the reformed communion. His works were translated into Latin into English. 'The Common Places of the most famous and renowned Divine Doctor Peter Martyr, divided into four principal parts by Anthony Marten,' dedicated to Queen Elizabeth, in 1658, with a biography of Vernigili by Josias Simler, of Zürich: this collection contains a complete course of Christian ethics, and may be read with advantage even now. (Don, Gardener's Dictionary; Babington, Manual of British Botany.)

VÉNET, ANTOINE CHARLES HORACE, commonly called Carle Vernet, a French historical, genre, and battle painter, was born at Bordeaux, August 14, 1758, and was the pupil of his father, Claude Joseph Vernet, the celebrated marine and landscape painter. He entered the French Academy at Paris, where he gained the second prize for painting when in his eighteenth year, and in 1782, six years afterwards, he obtained the grand prize, and with it the privilege of studying for a certain period in the French academy at Rome. In 1787 he was elected a member of the French Royal Academy of Painting for a large picture of the Triumph of Being at Naples; he became acquainted with Johann Widmann, a nobility of the academy, nominated a member of the Institute of France.

His principal works are—the large picture of the Battle of Marengo, and a battle against the Mamelukes, exhibited in 1804; The Morning of the Battle of Austerlitz, with the Emperor giving orders to his Marshals, and an equestrian portrait of Napoleon, in 1808; the Bombardment of Madrid,
the Battle of Rivoli, and another picture of the Emperor, in 1810; John Sobieski forcing the Turks to raise the Siege of Vienna, in 1689, exhibited in 1819; The Taking of Pampluna, The Entrance of Napoleon into Milan; and the Battle of Wagram.

Carle Vernet has painted also an immense number of pictures of horses, both the living and in motion, and of the most favourite subjects, as also many of the chase, of scenes of familiar life, and from the imagination. He was also a celebrated painter of horses, and by some considered the best of his time; among his pictures are many small equestrian compositions, several subjects of which are also inconsiderable, which exhibit a patrician air, and a spirit of freedom and imagination. He was in 1816 appointed painter to the Dépôt de la Guerre: and he was made subsequently Chevalier of the orders of St. Michel, and of the Légion d'Honneur. He died September 27, 1836. However, he was not able painter for the most prolific pencil of the present century, is the son of Carle Vernet, and was first instructed by him in his art.

(*Gobet, Dictionnaire des Artistes de l'Ecole Française au dix-septième Siècle.*)

VESTED REMAINDER. *Remainder, P. C.*

VIBRATIONS OF HEAT. *Heat, P. C.*

VIBRATIONS OF LIGHT are the movements conceived to take place among the molecules of an aetherial medium which is supposed to exist in space and even to occupy the interiors of bodies; they are the cause of the waves by which are obtained perceptions of light and vision; and the relations of these vibrations of the molecules of air by which sound is excited. From experiments which are alluded to in the article *Umboldt's Theory of Light,* P. C., p. 512 it has been demonstrated that, if we call the velocity of a wave, the squares of the velocity at the violet extremity is 0-00000062 inches, and for the light at the violet extremity is 0-0000107 inches; hence it follows that the number of undulations which are made in air, in one second of time, is, for the first kind of light, about 458 millions-and, and, for the last, about 277 millions, it follows that, if unity be divided by each of these numbers, the quotient will express the very small fraction of a second in which a complete vibration is performed in air by a molecule of the luminoferous aether.

The waves of sound move in air through less than 1200 feet per second; and it follows that the velocity of light is more than 900,000 times greater than that of sound; but the velocity of an undulation varies with the square root of the elasticity of the medium in which it is propagated; and hence it should follow that the elasticity of the luminoferous aether is to that of air in a ratio exceeding that of the square of 900,000 to unity.

Undulations of the luminoferous aether are presumed to take place within the substances of all refracting media, as air, water, glass, &c.; but it is probable that the vibrations of the aetherial molecules in such substances are modified by the vibrations of the molecules of the substances; the observed phenomena of refraction render it necessary to consider that the greater is the refracting power of a medium, the less is the elasticity of the aetherial molecules within it and the greater is the degree of vibration to which the waves of light are propagated through it.

The aetherial vibrations which, by affecting the retinae of the eye, give rise to the sensations of light, take place, as above stated, with great rapidity, but the impression made by any single vibration is inconsiderable; therefore, in order that the combined actions of the vibrations molecules may be sufficiently powerful to produce effects which are sensible, it is necessary to suppose that the vibrations are performed in equal intervals of time, the intervals depending on the nature of the vibrations of which the retina is susceptible; as in order to give motion to a pendulum by a repetition of very small forces, these must be made to act at the end of equal intervals of time which depend on the length and form of the pendulum. The particular colour of light is made to depend on the velocity of the aetherial molecules, or on the extent to which those molecules vibrate on each side of their mean places; and whatever be the number of vibrations made by the particles of ether in a given time, that is, whatever be the velocity of the vibrations, it is to be understood that the laws of the propagation of motion in elastic media, that the velocities of the waves of light are uniform in every direction. The intensity of the impression of light in the eye depends on the density of the aetherial molecules, or on the extent to which other aether vibrate on each side of its point of rest. *Umboldt's Theory of Light,* P. C., p. 510.

In common or white light, the vibrations of the aetherial molecules may be conceived to take place in any manner, but M. Fresnel assumed that when light is polarized, the eye is affected by a continuance of the aetherial vibrations. Therefore, if a series of vibrations be made with their planes in planes perpendicular to the direction of the motion of the wave or ray, the vibrations in this direction, if of the same nature, will reinforce each other, forming a bright line; but if of different natures, the vibrations will interfere with each other, and a dark line will be formed. The hypothesis is supported by experiments made on a pencil of light which, after diverging from a radiant point, is reflected from two mirrors inclined to one another at a very small angle, the waves of light are refracted so as to form a bright line; but when two plates of tourmaline having their axes at right angles to one another, which consequently polarize the light in planes at right angles to one another, are placed in the directions of the waves reflected from the two mirrors or transmitted through two faces of the prism, the waves cease to interfere with one another and no dark fringes are seen. It follows that no vibrations could have then taken place in the directions of the motions of the waves; since if they had, interferences ought to have been observed in the light which was polarized as well as in that which was not so.

For the composition of the vibratory motions in two polarized pencils of waves, similar experiments with electric vibrations are produced, see *Circular Polarization,* P. C. S.

VICTOR, CLAUDE FERRIN, Duke of Belluno and Marshal of France, was born at La Marche, in the Department of Calvados, in 1794, in the seventeenth year of age when, on the 16th of December, 1781, he enlisted as a private soldier in the 4th regiment of artillery, at that time in garrison at Amiens. He had obtained his discharge when the evacuation of the Revolution of 1789 occurred. He was, however, destined to more important and intrepid soldier to raise himself from the lowest rank to that of adjudant-major and chef de bataillon. With the bataillon under his command he distinguished himself at Jassy, by foiling the attack of three thousand Piedmontese and a regiment of emigrants. At the head of the same bataillon he obtained considerable success in 1793, at the siege of Toulon; under the orders of General Lafayette, he gained the important heights of Pharon, and afterwards, with similar good fortune, attacked the Fort de l'Aligüillotte, the capture of which greatly contributed to the favourable issue of the siege. These brilliant actions, in which he was twain wounded, were rewarded by his promotion to the rank of adjudant-general. Transferred to the army of the Eastern Pyrenees, with the rank of general of brigade, he rendered himself conspicuous in the defense of his army (June 22nd, 1794) and Rosas (January 2, 1795). After the termination of the war between France and Spain by the treaty of peace signed on the 22nd of July, 1795, Victor joined the army of Italy and commanded a division on the side of that campaign, and particularly in the action at Borghetto (May 30, 1796), brought him under the favourable notice of Bonaparte, who gave him every opportunity for further distinction by entrusting him with the management of manoeuvres as honourable as they were perilous. His conduct during the angiographical engagements which took place at Coassa and Mondovi (April 5 and 16, 1796) justified the high estimation in which he was held by his chief, and were recognised by the government at Paris in a flattering letter which they sent him. The following year, by a series of skillful manœuvre, he greatly contributed to the success obtained by Massena [Masséna, Marschal, P. C. S.] over the Austrian General Wurmser [Wurmser, P. C.] at Corona (August 11, 1797). It was on account of his successes during this campaign, of which we have enumerated a very small part in this, that he was raised to the rank of general of division. In this capacity he powerfully seconded the operations directed by General Lannes against the Papal States [Lannes, P. C. S.,] and after the enemy had been dispersed was intrusted with the command of the army which was composed of twenty pieces of cannon, and a garrison of five thousand degenerate Romans. General Victor," says Napoleon, "crossed
the Po at Borgo Forte, at the head of four thousand infantry and six hundred horse, and formed a junction, at Bologna, with the Italian division of four thousand men, under General Labez. By his skilful dispositions, and by his conciliatory, but firm and decisive conduct, he maintained the tranquillity of that country. Being recalled, in 1798, to the army of Italy, he was placed, by the head of a large corps of the army of Italy, to the command of the corps of the French army of Naples through the valley of the Formida; in effecting this movement, his division was attacked by a large body of Piedmontese insurgents, in the narrow and difficult passes of those mountains; his troops however bravely repelled this attack at the point of the bayonet, and, after surmounting great dangers, he was enabled to effect a junction with the army under the command of General Macdonald. [MACDONALD, MARSHAL, P. C. S.] Victor bore a distinguishe part in the engagement on the banks of the Trebisch, which proved disastrous to the French. He was afterwards sent to Paris by General Moreau, to solicit from the Directory reverses, and, after considerable length of time and many dispositions, he returned to Italy and assumed the command of his division, which acquired fresh laurels at the battle of Basano, where it formed part of the centre under the command of General Moreau.

At the memorable battle of Marengo, the division of Victor formed part of the advanced guard; to the bravery and perseverance which he displayed on this occasion may in a great measure be ascribed the favourable issue of this long-disputed engagement. His services were rewarded by the presentation of a sabre of honour, on which was inscribed a flattering testimonial to his merit. He was afterwards transferred to the Basan division of the army of Italy, and, in the territory of the Austrian kingdom, he conducted an army of his division in the campaign; his conduct in that campaign, though unmarked by any brilliant exploit, was such as to maintain the high reputation he had acquired.

After the peace of Amiens, he was sent to the court of Denmark as ambassador from the First Consul. He held this office till 1806, when, on the breaking out of the war with Prussia, he was appointed to the command of the tenth corps of the grand army. A wound, which he received at the battle of Jena, did not prevent him from directing in person the operations of the corps under his command during this short but brilliant campaign; and he powerfully contributed to the victory obtained by the combined forces of the Prussians and Russians at Pulstuck (December 26, 1806). In this campaign he was taken prisoner by a body of partisans, but, by means of an exchange, he speedily recovered his liberty. The country of the Harz, which he had the honour to visit, and the battle of Germany (June 14), in which Victor, at the head of the first corps of the grand army, so distinguishe himself, that Napoleon, on the field of battle, raised him to the dignity of Marshal of the empire.

After 1808 he was intrusted by Napoleon with the command of the first corps of the French army in Spain. Shortly after his arrival in that country he obtained important advantages over the Spaniards in the engagements of Epinosa (November 4), and Biscarrat (November 22). On the 13th of December, 1808, he routed the remnants of the Spanish army which had been defeated at Tudela [LARENS, P. C. S.]; but, which, reinforced by the French army which had been detached from the northern bank of the Ebro, had taken up a menacing position at Ucles. In this engagement upwards of three hundred officers, including two generals and twelve thousand soldiers, were made prisoners; all the troops on the right bank of the Ebro were effectually broken by the French. According to the Spanish accounts, this victory was obtained by the exercise of wanton cruelty towards the prisoners, in retaliation for similar cruelty exercised on the part of the French at the battle of Seringapatam. [See NAPIER, 'History of the Peninsular War,' vol. ii. p. 16.] At Medelin (March 28, 1809) Marshal Victor obtained another important victory over the Spanish army under General Cuesta, in which six thousand Spaniards are said to have fallen, and which, though claimed by the French, was never confirmed.

Afterwards sent with his division to the support of Marshal Soult in Portugal; but he had scarcely entered that country, when he was obliged to effect a retreat. Having retired to the coast of Josse (August 27), he was again recalled, and, under the command of General Jourdan, and General Sebastiani, he was induced to attack the army of Sir Arthur Wellesley, which was advancing into Spain. The issue proved disastrous to the French army; but after a long contest, in which the French lost General Elzanans and 5,000 men, they were defeated at Talavera de la Reya (July 28, 1809). This battle however did not materially change the position of the battle armies. [TALAVERA, F. C.] Victor having united his forces with those of Marshal Ney and Mortier, and the British army being obliged to retire before the superior numbers of the enemy, the French were again enabled to occupy the town of Talavera. To the credit of the French command of Talavera, it may be stated that a large number of sick and wounded English soldiers were treated with the greatest kindness.

On February 4, 1810, the duty of investing Cadiis was assigned to Marshal Victor, whose Napoleon had created Duke of Belluno; he conducted the operations of this siege with skill and perseverance, but though protracted for a long time, the position was not attacked. In 1812 he was summoned from the blockade of this town to join the grand army destined for the expedition to Russia, and was appointed to the command of the ninth division. His name stands conspicuous in the annals of the Russian campaign. [BONAPARTE, F. C.] During the retreat, he rendered the most important services to the French army, and in particular to the perilous passage of the Beresina (November 29, 1812), where, with six thousand men, he successfully resisted the efforts of General Wittgenstein [WITGENSTEIN, F. C.] and thirty thousand Russians. His courage in this action was rendered more remarkable by his humanity. Being recalled, on the approach of evening, from the position which he occupied at Stoudzianos, he took upon himself to disobey his orders, and remained there during the whole night, for the purpose of giving every assistance to the remnants of the French army, which had not yet effected the passage of the river. At daybreak, he skilfully managed to evacuate this position, without loss of either baggage or artillery, taking with him the wounded and a large number of camp followers, who, without his humane aid, must have fallen into the hands of the pursuing enemy.

The following year, Marshal Victor commanded the second division of Napoleon's army: to the conduct of that division at the battle of Dresden (August 26, 1813) the French there obtained has generally been attributed. With the same division he likewise greatly distinguished himself at the battles of Wachau (October 16, 1813), Leipzig (October 19, 1813), and Hanau. The occupation of the Rhine had been effected by the French army, Marshal Victor was actively employed in putting in an efficient state of defence the strong places of Aixme and the Bruche Comté; he also for a time served as chief of the division of the Russian army into France. Compelled at length to fall back upon the Meuse, he effected this movement with his usual skill. He afterwards rejoined the allies in the position they had taken up at St. Dizier (January 27, 1814), and drove them out at the point of the bayonet from the village of Brienne. During the whole campaign he zealously endeavored the efforts of Napoleon and the French army in checking the advance of the allies. On the 9th of February he marched his troops towards the Seine, for the purpose of more effectually co-operating with the movements of his chief, and sustained his high character as a soldier in the defence of the bridge of Nogent (February 11, 1814) and in the actions of Nangis (February 17) and Villeneuve-le-Rol. His failure in dislodging the allies from Montereau, where he had the misfortune to lose his son-in-law, was more than counterbalanced by the displeasure of the emperor, who deprived him of his command. The marshal, it is said, refused to leave the service, and observed with emotion to his chief, that 'he had once been a private soldier, and to be made a marshal was his ambition, and would again take his place in the ranks.' The emperor, moved by this proof of his fidelity, put him at the head of two brigades of his guard, with which he distinguished himself; a few days after the treaty of Chaumont, he was severely wounded, and was obliged to retire from the field.
When the success of the allies and the abdication of Napoleon had replaced the Bourbon dynasty on the throne, he was among the first to offer them his allegiance, and was accordingly appointed to the command of the second military division. On the return of Napoleon from Elba, he issued a proclamation, in which he allowed himself to speak of the new government in terms which reflect high discredit upon his character; he describes himself as 'the man who has tyrannized, desolated, and betrayed France during twelve years,' and he urges every Frenchman to pursue the unsuccessful tyrant, but 'his satellites who accompanied him on his plundering excursion.' Independently of the ingratitude which this language betrays, it evinces a singular want of discernment, coming from one who had been at the head of the most compact of these satellites. The latter part of this year followed the examples of Marshals Berthier [Berthier, P. C.] and Marmont in accompanying Louis XVIII., to Ghent. [Louix XVIII., P. C.] On the second restoration, he was created peer of France, and appointed one of the four major-generals of the royal guard. He was also unfortunately conspicuous as the president of the commission charged to inquire into the conduct of his former brethren in arms during the hundred days [Next, Marshals, P. C. S.]; in that capacity he is reported to have displayed an unnecessary and pertinacious severity. In 1816, Marshal Victor was appointed to the command of the sixteenth military division in France. In 1819, he was named Louis XVIII., minister of the war department; in this capacity he altogether disappointed the expectations to which his military talents had given rise; he alienated the affections of the people, and was described as 'a bloodthirsty old man,' and lost the little popularity he had hitherto enjoyed. He actively promoted the expedition to Spain of 1823 [Steicher, P. C. S.], and, having retired from the ministry, accompanied the army as a spectator in the campaign to the Duke of Angouleme. After the revolution of 1830, [Charles X., P. C. S.] he ceased to take any active part in public affairs; though he gave in his adhesion to the government of Louis-Philippe, he attached himself to the legitimist party, and appears on one occasion to have been seriously compromised, with several of the leading men of that party, in exposing the cause of the Bourbon claimant to the throne of France. He died on the 3rd of March, 1841.

The position occupied by Marshal Victor among the generals of Napoleon is not a very high one. Though his services to the Imperial cause were numerous and many of his exploits were brilliant, he is rather distinguished as a brave soldier than as a skilful commander. At the head of a division he executed with boldness and precision the movements indicated to him by his chief, but he was devoid of the military genius requisite to originate a skilful plan of battle. Hence, in a separate command, as in many instances in the Peninsular War, he was generally unsuccessful. He does not appear to have been actuated by the very great remark made concerning him by Napoleon, which O'Meara records: 'Victor était une lèbe sans talons et sans tête.' ('Napoleon in Exile,' vol. i. p. 511.) Such a judgment probabljly arose from the influence of the feelings which Victor's conduct, on his return from Elba, had excited. It is indeed scarcely possible that it was the real estimation he had formed of this general's military character, since he had raised him from the position of a private soldier to the highest dignities of his empire, dignities which were in every case the reward of some species of merit, and not the mere fancy of favouritism.

come to demand your assistance and the junction of your forces to ours, without which we can never expect to re-conquer Jerusalem; and, as we are resolved to undertake this conquest, we have been commanded not to leave your city till we have received a free answer to our message, by which you are to impose the conditions on which it is to be granted.

To this energetic appeal were joined the tears and entreaties of the other deputies, who, in the holiness of their mission, did not forget the shame of submission to the representatives of commercial power Moved by their appeal, and by the pecuniary advantages which were likely to result from the transaction, an unanimous declaration arose from the assembly of the <Nouns> favourable to our design. We were at length concluded with the French deputies and the Republic, by which it was agreed, that the Venetians should furnish the vessels necessary for the transport of 4500 horsemen and 9000 squires and attendants, and also 20,000 foot soldiers, with nine months' provisions; that the vessels should be equipped and ready to sail in the month of June in the following year, and that their service should only count from the time that they left Venice. For these services the crusaders were to pay the Venetians the sum of 80,000 marks of silver, or, according to some accounts, 85,000. The payment of so exorbitant a sum, for a period that prolonged the generous zeal of the crusaders and the attentive regard of the Venetians to their interests. After the conclusion of this treaty, Villehardouin returned to France, where he found the Count Thibault dangerously ill. The death of this noble warrior caused the crusaders without a chief. The command of the expedition having been offered to the Duke of Burgundy, and afterwards to the Count of Bar, who both declined it, it was finally assumed by Count Villehardouin, who appointed Venice as the place of general meeting.

The first exploit of the crusaders, after leaving Venice, was, at the solicitation of Alexis Comnenus, to re-establish on the throne of Constantinople, the Emperor Lascaris. The French having afterwards to complain of the conduct of Alexis, who had not ratified the stipulated conditions for the succour they had lent him, sent Villehardouin as their deputy to make the necessary remonstrances.

Villehardouin was present at the siege of Constantinople in 1204, when that city was taken by the Venetians and French [Constantinople, P.C.], and to him history is indebted for a minute and graphic description of this remarkable siege. He thus describes the impression which the first appearance of the imperial city made upon his rude companions in arms:—"That such a city could be in the world they had never conceived, and they were never weary of staring at the high walls and towers with which it was entirely encompassed, the rich palaces and lofty churches, of which there were so many that no one could have believed it, if he had not seen with his eyes the cities in that country, and know that there was not so bold a heart there that it did not feel some terror at the strength of Constantinople." Chap. 95. (See the notes at the end of xxiv. of the Waverley Novels, Edinburgh, 1827.)

The services of Villehardouin were rewarded by the Emperor Baldwin, whom the victorious Franks had placed on the throne, by his appointment to the important office of Marchal of the province of Romania. His military skill and bravery also insured him the esteem of the Emperor Henry, the successor of Baldwin, to whom the Marquis of Montmort had given his daughter in marriage; from him he received, as a free gift, the entire city of Messina, together with its dependencies. This valuable donation induced him to reside in Thessaly, where he died about the year 1213. While however enjoying the honours which his merit had acquired for him, he did not forget the interests of the country of his birth; in 1207, he richly endowed the abbeys of Fossoy and Troyes, to which his sisters and his two daughters belonged. The lavish of his name gave powerful influence to himself and his family. These two centuries ruled over the most important principalities of Greece.

It is chiefly as a historian that the name of Geoffroy De Villehardouin has become celebrated. To him we are principally indebted for the important facts of our periods in the wars of the crusades [Crusades, P.C.], from 1188 to 1207. His work is entitled 'L'Histoire de la Prise de Constantinople par les Francais et les Venitiens.' The author relates the events with a style which has given him just praise for his modest simplicity and tolerable candour. His narration is remarkable for brevity and clearness, and generally bears the impress of truth. His talents as a negotiator caused him frequently to be employed on missions of importance, and to be
ammonished to the council of the army; he has thus been enabled to give a minute detail of several events, of which we might otherwise have remained ignorant. His history rendered the more valuable from the fact, that it is probably the oldest historical record in prose which the French language possesses. The first edition of it was published at Venice in 1613, and Paris in 1586; but the most valuable is that which

by the learned Du Cange, "whose notes," says Mills, "are as valuable as his notes on the Alexiad." [BRITISH HISTORIANS. P. C.]

The title of this edition of Du Cange, which has not easily been noticed, is as follows:

"Histoire de l'Empire de Constantinople, divisées en deux parties, &c., écrite par Geoffroy De Ville-Hardouin, avec la suite de cette Histoire jusqu'en 1524, tirè du Manuscrif de Philibert de Chastillon, le tout par des observations faites par Charles du Fresne, Sieur du Cange; Paris, de l'imprimerie Royale, 1657, in fol." In this edition the old text is accompanied with a modern French version. The history of Ville-Hardouin is also to be found in vol. xxviii. of the "Recueil des Historiens des Gaules et de la France." Paris, 1823, in fol.: the text in this edition has been revised on three manuscripts, and it is appended a glossary.

(Vincent. De Paul, Saint.)

VINCENT DE PAUL, SAINT, was born on the 24th April, 1581, at Bananques in the province of Pouey, near the Pyrenees, in the present department of the Landes. He was the third son of Guillaume de Paul, who owned and cultivated a small estate, which was afterwards the means of his family's future prosperity. He was promised a life of laborious toil, and till the age of twelve he assisted his parents in the care of their farm. He had however from early youth manifested so great an acuteness of intellect and sensibility of disposition, that they were induced to endeavour to give him a suitable education. He was placed as a student in a convent of the Cordeliers at Agen, the residence of the bishop of his diocese. At the age of sixteen, he was considered qualified to become tutor to the children of M. de Commet, an advocate of Agen, and the magistrate of his native village. This situation enabled him at the same time to relieve his parents from the expenses attendant on his education, and to prepare himself for the ministry of the church, to which he had now determined to devote himself. He assumed the tonsure on the 20th December, 1606, and the next year he went to Toulouse, in order to follow the course of theology of that university. But he was compelled, on account of the slender pittance which was allowed him, to combine the duties of a teacher with those of a student. At the year 1609, after he had received a liberal endowment, he was made a priest by the Bishop of Perigueux: in the same year he was made the parish priest of Tilh, one of the most valuable in the diocese of Agen, which he visited twice a year in order to devote himself more entirely to the study of theology. In this study, notwithstanding the difficulties under which he laboured, he soon became eminent, and on the 12th October, 1604, obtained the degree of bachelor of arts, which he was permitted to lecture on. In 1605, a legacy of fifteen hundred livres, which had been left him by a friend who had died at Marseille, compelled him to make a journey to that city. After taking possession of his legacy, he was returning to sea, when he was taken prisoner by some Tunisian corsairs, and was wounded in the conflict. He had left a minute relation of his capture and imprisonment, in a letter written to his early patron, M. de Commet, on his return to France in 1607, of which there is a copious extract in the "Biographie Universelle." During his captivity at Tunis and Algiers, he became the slave of three successive masters; the last of them, an Italian renegade, and nephew to his former master, was induced to his deliverance after a delay of ten months, when he was sufficiently fortunate to induce his master to forego the temporal advantages of a residence in a land where he was obliged to conceal his profession of Christianity, and to escape with him to France. There he remained until in the course of the year 1609, when he took leave of the confreres of the Diocese of the pope, Paul V., who had performed this ceremony. He induced Vincent and his companion to accompany him to Rome. He there became acquainted with the ambassador of the pope, who selected him an important and confidential messenger to Henry IV. He arrived in Paris at the commencement of the year 1609, and obtained several interviews with the king. His time however he chiefly devoted to the service of the sick of the Hôpital de la Charite, and of his frequent visits to the prisons.

The period of Vincent's residence in Paris was emblazoned by an accusation of robbery made against him by a fellow-lodger, a native of the same province as himself, and for six months he was confined in the house of correction. Man of his time, though suffering severely from the cruel imputation, he contented himself, when questioned concerning it, with a simple denial, joined to the remark that 'God knew the truth.' During the first part of this confinement, he was removed, and the reputation of Vincent rose still higher in the estimation of those who had witnessed the patience and resignation which he had displayed under the false accusation. His short residence in Paris was followed by one of as active service, and the support of several influential personages, whose friendship and esteem his merit had conciliated. Among them was Marguerite de Valois, sister of Henry III., and the divorced queen of his successor, who appointed him her almoner, and Pierre de Berulle, afterwards cardinal, and founder of the congregation of the Oratorians. By the latter he was induced to accept the care of the parish of Cligny in the neighbourhood of Paris, where he discharged his duties with exemplary diligence. His short residence in that village was blessed with the happiest results: not only were the sick attended, the poor assisted, and the afflicted consoled, but family discord and dissensions and religious matters were made by his piety influence to cease.

In 1613, he was obliged to abandon this peaceful scene of spirituality, and to undertake the education of the three sons of Philippe Emmanuel de Guise. The task was one of the general of the galleys of France. These pupils of Vincent were destined to occupy an important position in the history of their country: one of them became the well known Duc de Rennes; another, the famous cardinal, who acted so conspicuous a part in the civil wars of the Fronde. [Renz, P. C.]

In 1616, he accompanied the Comte de Joigny to her country residence at Folloure, in the diocese of Amiens. where he commenced a series of missionary labours among the inhabitants, which were eminently successful. The memory of this mission he was in the habit every year, on the festival of the conversion of St. Paul, of celebrating with piety gratitude. The following year, he left the residence of the Comte de Joigny to undertake the care of the parish of Châtillon, in Bresse, where his labours were attended with similar success. It was there that he first established and organized a religious association for the relief of the temporal and spiritual wants of the sick and poor, to which he gave the name of the "confrérie de charité," which he afterwards extended to other countries. Towards the end of the same year, he was induced to return to the Count's family, and, with the permission and co-operation of the Count, a lady of pious disposition, and who was the more important to Vincent, under his spiritual direction, he undertook several successful missions in the dioceses of Beauvais, Soissons, and Sens. An opportunity was now afforded to labour in a cause still more noble and extensive, and which presented the most danger, disappointment, and difficulty. He was in the habit of accompanying the Comte de Joigny, whose situation as commander of the royal galleys rendered it necessary for him frequently to visit that city. He was there more occupied with compassion on witnessing the sufferings and severities to which were subjected the unhappy criminals condemned to the galleys. To ameliorate their condition and to alleviate their sufferings was the pious task which Vincent took upon himself. He found them in narrow and unhealthy dungeons, almost entirely deprived of air and light, with bread and water for their only food: disfigured by filth, and covered with vermin, they were there deprived of the means of personal comfort and relief. In their most ignominious position, he would visit them, and, by the rude scoffs and jests to which he was at first exposed, and undismayed by the harrows of a pestilential disease, which was the prevailing evil of the period, he unswervingly pursued his charitable mission; his kindly words were anotice to their wants, his reproves, tempered by mildness in Christian charity, and, above all, his own example of humility and self-sacrifice, which convinced his hearers of the great and increasing gaining his confidence, and thus secured a ready acquiescence in his efforts for their welfare. In a short time, the most unexpected
success attended the improvements which he introduced and the reformation which he effects. The augmented condition of these criminals was sensibly felt and gratitude acknowledged by his patron, who called the attention of the King, Louis XIV, to the means and abilities of his protégés of criminals under his care and to the devoted man by whom it had been produced, and the king, with appropriate consideration for the services he had rendered, appointed Vincent almost immediately to a position of the highest importance. This appointment to an office of the Order of the Visitation, which he had lately established.

In 1628, Vincent established two congregations of clarisses in the town of Dijon, one for men and the other for women. He next visited the city of Bordeaux, for the purpose of inquiring into the condition of the criminals there confined to the galleys. On leaving that city, he visited his friends and relations in his native village; having assembled together those who remained of his family, he informed them of his determination to die as he had lived, destitute of all worldly wealth; told them that money left by a priest to his family would prosper, and thus cleared them of every suspicion they might have formed of obtaining property at his death.

This resolution however did not prevent him, on a subsequent occasion, from distributing among them about a hundred pounds of money, which had been given to him for another purpose. The next scene of Vincent's labours was the town of Chartres, where he founded an association under the name of the Congregation of Lazarists, a branch of which was established in the provinces of France with efficient teachers of religion, who were to act as instructors to the regular clergy, and to be subordinate to the authorities of the church. On 6th March, 1624, the Collège des Bon Enfants was given to him as the first residence of the new company he had formed. For the better watching of his infant institution, he left the family of the Count de Joigny, and retired to college. In 1627, he had the highest credit and the most important regulations of the Missions authorized by letters patent from the king, and in 1631, formally approved by a bull of the Pope Urban VIII. During this period he was actively employed in establishing retreats for the members of the society, and for persons destined to enter the orders of the church; a measure which greatly tended to the reformation of many existing abuses. In 1632, he yielded to the repeated requests of the Prior of St. Lazarus, Adrien Lebon, to accept his house and property for the purpose of furthering his projects for the instruction and relief of the poorer classes of the peasantry. Small as were the beginnings of this institution, it lived to see the orders of Lazarus and the Lazarists become the most illustrious branch of the society and the most productive of charitable institutions in the greater part of Europe. The institution however which has probably been the most beneficent consequences that was the establishment in 1634; it was composed of a considerable number of men who were educated, and especially devoted themselves to the attendance of the sick; a branch of this society, called les Dames de la Croix, was intended for the sole service of the Hôtel-Dieu at Paris. To Vincent de Paul this city indeed has been peculiarly indebted for many valuable institutions, whose utility is recognised to this day. Among them may be mentioned the hospitals of la Pitié, la Bicêtre, la Salpêtrière, and les Enfants Trouvés, or Foundling Hospital. [Paris, P. C.; Foundling Hospital, P. C.] The origin of this last-mentioned institution exhibits a striking proof of the disinterested zeal of Vincent. Previous to the establishment of the Foundling Hospital, in 1626, the infant children were put to the misery of the streets and public places of the city, and often left there to perish. The pitiable condition of these innocent children excited the compassion of Vincent, and often stimulated the charitable zeal of this devoted minister of the church. For the purpose of affording them food and succour he enlisted in his cause several ladies of the capital, over whose finding of a sufficient sum for the support of the poor children, he called them together at the commencement of the year 1640, and so energetically set before them the motives for their charitable intervention in the cause of these unfortunate beings, that some of the most devoted amongst them, and some of the ablest were about to abandon their charitable enterprise. To avert so unhappy an issue to his charitable project, in 1648, Vincent called together another and more numerous assembly. He there summoned to their aid a number of the first men of the city, and urged in support of his cause, and pleaded the interest of these innocent outcasts of society in a language of fervent and impassioned eloquence; an eloquence unaided indeed by the arts of a polished tongue, but which, by the irresistible force of deep-seated sincerity and ardent zeal, the termination of his address on that occasion has been recorded by a high authority as one of the finest pieces of eloquence in any language. [Mauri, Essai sur l’Eloquence de Vincent de Paul, P. C.] Rich and plentiful were the fruits of his energetic pleading; alms were collected in abundance, two large buildings were converted into hospitals for foundlings, and the capital of France was no longer disgraced by the daily exhibition in its streets of helpless children dying from the want of food and succour. Besides the hospital already mentioned, Vincent founded two others, which have been productive of considerable benefit; one at Paris, which went under the designation of the name of Jesus, for the maintenance of forty poor men, whose age had incapacitated for labour; the other, the Sainte Trinite, in the diocese of Avignon, in Burgundy, was for the support of the poor over the number of the numerous pilgrims who are accustomed to visit the shrine of that martyr. While occupied in the formation of societies and in the establishment of institutions destined for the permanent relief of his fellow-creatures, he was no less zealous and persevering in attending to the immediate wants of those who came within the reach of his assistance. The province of Lorraine was, during the latter period of the reign of Louis XIII., suffering under the threefold calamity of war, pestilence, and famine. To this province, by his charitable exertions, for several successive years, Vincent caused considerable sums of money, which he collected in Paris, to be sent for the succour of its inhabitants. His biographers differ with respect to the amount, the highest stated being two million livres, and the lowest from five to six hundred thousand.

During the wars of the Fronde, the Queen-regent, Anne of Austria, instituted a council for the settlement of disputes on questions of theology, and appointed Vincent de Paul its president. In this capacity, he took a prominent part in the religious controversies of that period, and warmly espoused the cause of the Jesuits against the followers of Jansenius. [Jansénistes, P. C.; Port Royal, P. C.] Through his influence, a letter was obtained from the Pope, recommending the reigning pontiff, praying him authoritatively to condemn the witness of Jansenius, and in particular the work entitled Auguries. In carrying on this controversy however, he never concealed the fact that he had been employed against his adversaries only the legitimate weapons of argument and ex postulation. The four last years of his life were spent under the burden of infirmities, which compelled him to keep within the precincts of the convent of St. Lazarus, where nevertheless he continued sufficiently to preside over the interests of the community he had established. His death, which occurred on the 27th September, 1660, was preceded by severe and protracted sufferings, which were borne with his accustomed patience and resignation. His remains were deposited in the church of St. Lazarus, in presence of the assembled clergy and the nobility of the land, who as a mark of respect and esteem of their spiritual father; but perhaps the tears of most genuine affection were shed on his tomb by the multitude of the poor and needy, who gratefully remembered that they had been long consoled by his counsels and relieved by his charity. The panegyric of this eminent minister of the church has been written by two of its most distinguished prelates, Father Louis de la Balue, Bishop of Tarn, and Father Louis de Saulx, Bishop of Grenoble, and has been the subject of the highest eulogium and commendation. The last of these has been greatly admired for the beauty of its style and the energy of its expressions; it may be seen in the last edition of his Essai sur l’Eloquence de la Chaire, xxxvi, p. 321; by Pierre Mauri, P. C.; and in his death was consoled by a ceremony, known in the church of Rome by the name of Beatification, by Benedict XIII., on 14th August, 1739, and he was canonized as a saint on 16th June,
the name of St. Vincent de Paul stands deservedly high in the list of benefactors of mankind. His entire life was devoted to the advancement of the best interests of humanity; he labored, not only as the creator of a new scene of alleviate poverty and suffering, poverty and crime, and his presence was always attended by conciliation and relief to their victims. Men of all creeds and persuasions have rendered homage to his worth, and he is held in the highest esteem by his own church, which knoeks to the people of St. Vincent de Paul for the power of working miracles. The greatest miracle however himself, and the mighty works of which he was the instrument; the many hospitals which he founded, the reformation of the order by which he established the missionamines whom he sent abroad, the vast sum of money which he caused to be distributed to the poor and sick, his untiring activity in ministering to their wants, his disinterestedness and self-denial, his evangelical patience and religious resignation; above all, his genuine humility, which, while it shed lustre on those of his charitable deeds which are known, has caused a large proportion of them to be unknown and unwritten, save in the records of the book of life;—these, it must be allowed by all, are the real miracles on which stands the lime of this apostolical man.

The following is a list of the writings he has left:—I. *Regulae sunt Constituenses concumae Congregatio Missionum*, Paris, 1858; 2. *'Le Utte au Pape Alexandre VII.*, pour solliciter la Canonisation de Francois de Sales, prince-episcop de Geneve; 3. *Conferences spirituelles pour l'obtention des Regnes des Seurs de la Charite; Paris, 1829, 2 vols.

The two most important biographies of St. Vincent de Paul are those of Abelly, who was intimately acquainted with the saint, and of Collet, who was a member of his community; there is also a third, by M. de Cospedepo, Paris, 1827, in 8vo.

*Vincularia*. A species of fossil Zeophyte is referred to this genus of Deformye from Fortlock, from the carboniferous limestone of Ireland.

Viner, Charles, died June 5, 1756, at his house, Aldershot, Hampshire. When or where he was born has not been ascertained. He is known as the author of *A General and Complete Abridgment of Law and Equity*, 24 vols. folio, 1741-1751, and as the founder of the Vinerian Professorship of Common Law in the University of Oxford. The *Abridgment* was written in his own house, at Oxford. The whole work is an Index, by a Gentleman of Lincoln's Inn. It appears to have occupied only ten years in printing, but Viner was probably occupied many years previously in preparation. Blackstone says he was half a century about it. This stupendous work was reprinted in 24 vols. roy. 8vo., 1792-1794, and was followed by 6 supplemental volumes, roy. 8vo., 1799-1806, the compilers of which were James Edward Watson, Samuel Comyn, James Sedgwick, Henry Alonson, John Wyatt, James Humphries, Alexander Anstruther, and Michael Nolan.

Viner having resolved to dedicate the bulk of his property, as well as the benefits of his profession to the public service of his country,' bequeathed by his will, dated December 29, 1755, about 12,000£ to the Chancellor, Master, and Scholars of the University of Oxford, to establish a Professorship, and to endow such Fellowships and Scholarships of Common Law in the university as the produce of his legacy might be thought capable of supporting. The Professor is to read a lecture in the English language within a year after his admission to the fellowship and scholarship of the university, and the volume of his lectures is to be published, and is to be inserted in the scholar, and the volume of every year in full course. The term is to consist of at least twenty-four lectures, to be read in one and the same term, with such intervals that not more than four are to be read in a week, and the reading of the whole course of twenty-four years is reckoned as one term. There are at present (1846) two Fellowships with 50l. a year each, and five Scholarships with 50l. a year each. Both Fellowships and Scholarships expire at the end of ten years after each election.

Blackstone was elected the first Vinerian Professor. He had commenced his lectures on English law in the year 1756, and continued them two years, and in the latter part of his course he felt that Blackstone's lectures gave him the hint for the foundation of the Professorship. The succession of professors is as follows:—1756, William Blackstone, D.C.L.; 1790, Richard Viner, D.C.L., 2. *Lectures on the Law of England*, 3 vols. 12mo., 1753, James Blackstone, D.C.L.; 1824, Philip Williams, B.C.L.; 1843, John Robert Kenyon, D.C.L.

*Chamber's Biographical Dictionary; Oxford University Calendar, 1846.*

*Biolinn Strings.* [Catulle, P.C.S.]

*Vita.* (In honour of M. de Visme, a Lieben merchant), a genus of plants belonging to the natural order Hypericaceae. The calyx is five-parted, usually villous on the inside. The berry membranous, the styles 5, stigmata 5. The stamens are numerous, disposed into 5 bundles opposite the petals, alternating with 5 glands or scales. The anthers are small, roundish, 2-celled, bursting lengthwise, the sepal with a double covering. The leaves usually protected with a dusty down, rarely with pollen dust. *V. guianensis* is a small tree with a stem about eight feet high, the leaves ovate, lanceolate acuminate, dilated at the base, rufous beneath, smooth above, filled with transparent dots. The flower is short, the calyx tubular, the corolla with 5-cleft, villous ciliata margined. The yellow berry, ovate, soft, and somewhat 5-cleft, covered. The bark when wounded yields a gum resin, which when dry becomes hard, and resembles gamboge. The leaves and fruit likewise yield a similar acetum. It is used in medicine as a purgative, in doses of from 7 to 8 grains. A decoction of the leaves is recommended in intermittent fever. This species is native of Guiana and Bengal. There are about twenty other species growing in the East Indies, Bengal, and Guiana: those from Guiana yield a resinous gum, which finds its way into Europe under the name of American Gamboge.

*Viturvius Britannicus.* [Gandon, James, P.C.S.]

Vittorino da Feltre, born in 1379, at Feltre in North Italy, studied at Padua under the celebrated Guarino of Verona, and afterwards became professor of rhetoric and philosophy in the same university. Being some time after invited by G. F. Gonzaga, lord of Mantua, to superintend the education of his children, Vittorino repaired to Mantua, where a separate and commodious residence was prepared for himself and his pupils. Here Vittorino formed the plan of a species of distinctiion repaired thither in succession to avail themselves of Vittorino's instruction, and among them Federico di Monte-feltro, afterwards duke of Urbino, Gicerto, prince of Correggio, Duke Alberico di Feltre, afterwards bishop of Reggio, Lodovico Torres, and Bernardino Brenzoni, who became afterwards celebrated as jurist, Theodore Gaza and George of Trebisonde, Ambrogio Traversari, or Camouledia, who visited the school of Vittorino at Mantua, giving in his Epistles (lib. vii. viii.) an interesting account of his system of education; and Carlo Ioinini, who died lately, has written a work on the same subject, entitled *'Itta dell' istoria prendente nella vita, a disciplina di Vittorino da Feltre a de' suoi discepoli.*

It appears from the example of Vittorino, of Guarino Veronese, and others, that education, in the larger sense of the term, was better understood in Italy in the fourteenth century than it has been since, but it was confined to the upper classes. Gymnastics formed a part of Vittorino's system. He lived with his pupils and took his meals with them. Their fare was wholesome but plain. He had tabules of various colours to teach his younger pupils the rudiments of reading. His older pupils were instructed in rhetoric, mathematics, and ethics. He was very strict with regard to their morals. He watched the discipline of his students with jealous care, and showed them how to handle the club. He loved them like a father. Such was the character of this distinguished preceptor.
VOLPI, GIAN ANTONIO, born at Padua in 1686, studied in his native town, and became a good Latin and Greek scholar. In 1717 he and his brother Gaetano Volpi established a printing-press in their house for the purpose of bringing out correct editions of classic authors, and they engaged for their assistant the printer Giuseppe Comino. This press—known by the name of Volpi-Cominiana, produced among others a valuable edition of Catullus with copious notes. The edition was much commended by scholars, and the city of Verona struck a gold medal, which was presented to Volpi; the title is, 'Calus Catullus Veronensis et in eum Jo. Antonii Volpii novus Commentarius,' 4to, Padua, 1737. Volpi afterwards edited Tibullus and Propertius. He translated from the Greek into Italian the dialogue of Zacharias Scholasticus; he wrote a dissertation on the satire of the Romans: 'Liber de satyras Latinae naturae et ratione, item paraphrasis perpetae et commentarii uberrimae in X satyras Juvenalis,' Padua, 1744; he edited the poems of Sannazar, with a biography of the author; he published a new edition of Dante; and he wrote three books of Latin poems, to which he added those of his ancestor-and namesake Gian Antonio Volpi, the elder, who was bishop of Como and was one of the Fathers of the Council of Trent. Volpi was for many years professor of philosophy and of rhetoric in the University of Padua. In his old age he became blind, and he died in 1766. His brother Gaetano Volpi edited Sallust in 1722, and he was an active assistant to his brother at the press. He wrote an account of their joint labours: 'La Libreria dei Volpi e la Stamperia Cominiana.' Giuseppe Comino having died in 1752, his son Angelo Comino continued to carry on the business. Another brother of Volpi, named Giuseppe, undertook the continuation of Cardinal Corradi's great work, 'Vetus Latium proficuum,' which he completed.

(Tiraboschi, Storia della Letteratura Italiana, with the continuation by Lombardi.)

VOLEZIP, a genus of fossil (coniferous?) plants which occurs in the Magnesian limestone of England, and in the new red sandstone of Germany. (Bromiart.)

W.ROBEET, ROOBERT, MASTER.

The name of this early Anglo-Norman poet is variously written in different manuscripts of his poems, and in the ancient writings which make mention of him. The most usual forms are Wace, Gasse, Gasso, Gauze, Guxo, and Hulstace, names which appear to be abbreviations of Eustache or his race. His Christian name is likewise doubtful, as he never styles himself otherwise than 'Master Wace.' Du Cange supposed it to have been Matthew, and Huet is the first writer who calls him Robert. He was born in the island of Jersey about the year 1112, and received his early education at Caen; he completed his studies, which appear to have been chiefly connected with the clerical profession, during a residence of some time in the territories of the King of France, and he afterwards returned to Caen, where Henry I. usually held his court. In this town he spent the greatest portion of his life; his chief occupation was the composition of metrical romances, so called from their being written in the Roman or vulgar dialect. The 'Roman du Rou,' which he completed in 1160, was dedicated to Henry II., and was presented to him by Wace in person, who was rewarded with a canonry in the cathedral church of Bayeux; this prebend, according to the ancient capitularies of that church, he held from 1161 to 1171. As he frequently styles himself 'cleric liant,' reading clerk, it has been supposed that he was attached to the private chapel of Henry II. He is, however, and that that was bitterly, that the reward he received from the Dukes of Normandy neither answered his anticipations nor came up to the promises they bad made him. He is said to have died in England, about the year 1184.

The principal details in this brief notice of the life of Wace, are given to us by himself in his 'Roman du Rou.'

"Lange est la geste des Normans, / A sa source est grave ou Roman. / Si l'on demande qui se fit ? / Kei! ce sont les vers qui sont subtils. / Julj de faute, ke j'ont, / Wace, de l'isle de Grece, / Kei est en mer vers accident. / Al fow del Normandy appele ? / En forme de langue il ne. / A Caen fu-tu les paroles, / Hancet fu-tu en brises mites, / Poit du langue en France apres, / Quand de France je repartis. / A Caen haisse conversal ? / D'Amiens a livre de Normamy. / Musi qui en scire et mult en fie. / Per Cet en s'ar et fer Rel. / Auvers: en fis si servir se de. / Me foi devant, Das en sentences. / A Rahims use enm present. / Hert prepare vos die. / Neun Hesit, per Hesit."

The rhymed chronicle from which this extract is taken is entitled 'Le Roman du Rou (Rollo) et des Ducs de Normandy,' and is the best known of the writings of Wace; it is held in high esteem as a monument of the language and as a historical document, which, though incorrect in some of its details and sometimes inexact in its data, presents a faithful picture of society during that period. It contains the history of the Dukes of Normandy from the first invasion by Rollo down to the eighth year of King Henry I., and not simply, as Hallam states, the narrative of the battle of Hastings and conquest of England by the Normans. The first, or introductory part, is written in lines of eight syllables, and presents us with the history of the first irruption of the Normans into England and France. The second part or section is written in Alexandrine verse, and relates the principal events which took place in the reign of Rollo; the third, in the same metre, the history of William Longsword and his son Richard, the first Duke of Normandy of that name; in the fourth part, which is alone longer than the three preceding, he describes the exploits of William the Conqueror, presents us with the sequel of the history of Richard, and that of his successors to the year 1106. [NORMANDY, P. C.] The whole poem contains exactly 15,547 lines. He generally follows Dudo and William of Jumièges in his choice of his sources. The translation is:

"Longue est la geste des Normans, / A sa source est grave ou Roman. / Si l'on demande qui se fit ? / Kei! ce sont les vers qui sont subtils. / Julj de faute, ke j'ont, / Wace, de l'isle de Grece, / Kei est en mer vers accident. / Al fow del Normandy appele ? / En forme de langue il ne. / A Caen fu-tu les paroles, / Hancet fu-tu en brises mites, / Poit du langue en France apres, / Quand de France je repartis. / A Caen haisse conversal ? / D'Amiens a livre de Normamy. / Musi qui en scire et mult en fie. / Per Cet en s'ar et fer Rel. / Auvers: en fis si servir se de. / Me foi devant, Das en sentences. / A Rahims use enm present. / Hert prepare vos die. / Neun Hesit, per Hesit."

riv fixed facts, but he adds many interesting and curious details which are of considerable importance and which are not usually included in other histories. His description of the battle of Hastings [WILLIAM L. P. C.] is given with considerable minuteness of detail, and has been largely drawn upon by succeeding historians. Among the most noticeable features of the English labourers' song, Wace says that they could not fight on horseback, nor shelter themselves under a buckler with one hand, while with the other they directed their blows against the enemy.

The other two extant poems of Wace are—1. 'Le Brut d'Angleterre,' a work which preceded his 'Roman du Rou.' The date of it is ascertained by the following lines near the end of the poem:

"Le Brut d'Angleterre, / A work which preceded his 'Roman du Rou.'"

The principal incidents in it are derived from a Latin translation, by Geoffrey of Monmouth, of a poem composed in the dialect of Lower Brittany. The subject of it is a certain Brutus, who is imagined to have been the great grandson of Zeus, and who ruled over Great Britain. It contains nearly eighteen hundred lines, in the same metre as those above quoted, and is by some supposed to have been the first work containing the origin of Arthur's round table, his knights, and tournaments. [ARTZIB, P. C.]

The next authentic work of Wace is styled 'La Chronique accomplie des Ducs de Normandy.' It commences with Henry II. and goes back to Rollo. It is a short poem of only three hundred and fourteen Alexandrine verses, and is published in the first volume of the 'Mémoires de la Société des Antiquaires de la Normandie,' p. 144. It must have been written later than 1173, as it makes mention of the troubles excited in Normandy during that year by the revolt of the sons of Henry II. against their father.

The other extant poems of Wace are three—1. 'Les Chevalier du Lion,' 2. 'Le Roman du Rouen,' and 3. 'Le Roman d'Alexandrie'; but, though they are undoubtedly productions of the twelfth century, they are now generally supposed by the best critics not to belong to the works of Wace.

The manuscripts of his poems are very numerous; there are complete manuscripts of the 'Roman du Rou' both at the Royal Library of Paris, No. 7567, and at the library of the Royal Arsenal; a few volumes, of the Royal Library in London, have been written in the fourteenth century. The most antient in the British Museum, and was probably written in the first years of the thirteenth century; it contains however only the fourth part of the 'Roman du Rou.'

There is a valuable essay on the manuscripts of the 'Roman du Rou' by M. de Bresquigny, in the fifth volume of his 'Notices des MSS. de la Bibliothèque Royale.'

In 1827, there was published at Rouen a 'Le Roman du Roi du Chevalier au Lion,' and 'Le Roman d'Alexandrie,' but, though they are undoubtedly productions of the twelfth century, they are now generally supposed by the best critics not to belong to the works of Wace.

The following works may be consulted for a more ample account of the life and writings of Wace:—1. Capetigue, 'Essai sur les Invasions Maritimes des Normands dans les Genêts,' 1828; 2. Depeup, 'Histoire des Expeditions Maritime des Normands,' 1826; 3. Wheaton, 'History of the Normen,' London, 1831. In these two works there are copious and interesting extracts from the 'Roman du Rou.' Depeup particularly has very justly appreciated the value of Wace as a poet and an historian. 4. Pluquet, 'Notice sur la Vie et les Ecris de Robert Wace, suivie de Citations extraits de ses Ouvrages,' Rouen, 1844. In this work will be
WALKING WHEEL is a cylinder which is put in motion about an axle by the weight of men or animals; it is used for the purposes of raising water, grinding corn, and various other operations for which a moving power is required. It is probable that a wheel was in general use in Egypt, in the East, in a very early age, to raise water; for Moses reminds the posterity of Israel (Deuteronomy xi. 10), that in Egypt they served their seed and watered it with the foot. A garden of herbs was made in China, and raised a plant for raising water to the higher grounds on which rice is grown. In a treatise on machines, which was published at Nurnberg in 1601, there is a description of a revolving wheel which was used in the construction of an inclined plane of a circular form, and turned upon an axle placed obliquely to the horizon, the axle resting at its lower extremity upon a horizontal fire-place, and at its upper extremity, in one which was attached to a part of the building in which the machinery was contained. The wheel or plane was made to revolve on its axis by men, who, while stepping on its upper surface pressed with their hands against horizontal rill and with their feet against slips of wood which were nailed to the surface in the direction of the radii; and, below the wheel was a pinion whose leaves, acting against the cog of a trundle on a horizontal shaft, gave a revolving motion to the machinery.

A similar kind of walking wheel was at one time proposed in this country, but it does not appear to have been much employed with France has a kind of walking wheel rendered invariable at the will of the person employed to give it motion; and consequently the danger of accidents from a failure of the machinery might be considered as obviated. Such a wheel would be constructed of an oval and a place on it, to put his power in equilibrium with different degrees of resistance; thus, when the resistance is great, he may walk near the circumference of the wheel, and when the weight of the man or the small, he may find a place more towards the centre at which he may act with most convenience to himself; but a serious objection to it is, that the force arising from the weight of a man being oblique to the surface of the plane, its effect in giving motion, compared with that of an equal weight applied at the circumference of a vertical wheel of equal diameter, is only as the sine of the inclination of the plane to the horizon (about 30 degrees) is to unity; therefore the former effect is only about half of the latter. The weight of the man or men employed to walk on a large wheel of this kind causes its plane to bend; and, when, in order to prevent this effect, the wheel is supported by vertical props, the friction is greatly increased, notwithstanding the application of friction rollers at the points of support.

Wheels for drawing water from deep wells, as well as for other purposes, were at one time constructed in the form of hollow cylinders or drums, the horizontal rim of which that blows with little interruption throughout the winter and spring down the valley of the Oxus, is unfavourable to vegetation. Their fleek of sheep and goats constitute the wealth of the country, and which are kept for other purposes, such as shawls of Cashmire are made. The horses are small, but strong. Of quadrupeds, wolves, foxes, and hares are mentioned. There is also a kind of wild sheep called Kutch-har, which is of the size of a two-year-old colt, and has splendid curled horns; in autumn, when this animal is in prime condition, no venison is better flavoured. It lives in hordes of several hundreds. The skin resembles the hide of a cow with the fleece of a sheep. There is still another animal found in the adjacent mountains called Russ, which is described as being larger than a cow and smaller than a horse, and has immense horns; it appears to be rare. The population of the valleys depends largely upon the increase of their flocks; in the statement of Lieut. Wood. The Wakhan boas being descended from Hazrat Zekonder, or Alexander the Great, but Lieut. Wood did not discover any difference between them and the cheetahs in the plains of Turun, whose language they also speak. The chief of Wakhan is dependent on the sovereign of Kunduz; but this dependence appears only to be nominal, except that he sends an annual present to the Amir, and has the right of fishing in the lake, which leads eastward to the town of Yarkand, in Chinese Turkestan, and westward to Kunduz and Balkh, and thence to Bukhara, Kabul, and Candahar. The chief of Wakhan (Wakhem; Wood, Journey to the Source of the River Oxus). WALCHIA, a genus of Lycopoidea fossil plants from the coal and oolite formations. (Bremberg.)
Wallace, William, a mathematician of considerable eminence, was born September 28th, 1768, at Dysart, in Fifeshire, N.B., in which town his father, a manufacturer of leather, lodged. He received the rudiments of education at a dame's school in his native town, and, at seven years of age, he was sent to a school in which, under a master, he acquired the power of writing, but to his father he was indebted for instruction in arithmetic. In 1784 his father, after the failure of his business at Dysart, having gone with his family to reside at Edinburgh, he was placed with a bookbinder in that city, to whom soon afterwards he was bound as an apprentice, but he failed to continue it, and, though he continued to have the benefit of his father's moral superintendence, as well as advice and assistance in the prosecution of his studies. Without any encouragement from his master the youth derived some advantage from the opportunities which he occasionally presented himself of perusing the books which he was employed to bind; and having, besides, found means to purchase some mathematical works, he succeeded in making himself master of their contents. It is said that before he was twenty years of age he had acquired a knowledge of elementary geometry and trigonometry, algebra with fluxions, conic sections, and astronomy.

About the age of five he became acquainted with a man who was employed by Dr. Robison as an assistant in making the experiments by which the subjects of his lectures were exemplified; and, when the term of his apprenticeship expired, he seemed naturally to find a place in the society of the distinguished professor. Dr. Robison finding, after an examination, that the young man had attained to considerable proficiency in mathematical science, and being made acquainted with his humble condition in life, kindly permitted him to attend the course of lectures on Natural Philosophy which was then about to commence. Of this permission he thankfully availed himself, and he regularly attended the class, though, in order to be enabled to do so, he was obliged to labour in his vocation during a portion of the time which should have been given to repose. Dr. Robison soon afterwards proposed to him to give lessons in geometry to one of his own pupils, a young man engaged in his business, and he, taking an interest in his welfare, contributed both by advice and by loans of books to facilitate his progress in acquiring a knowledge of the higher branches of mathematics. For some time the prosecution of his studies, Wallace quitted the calling for exercising which he had qualified himself by serving an apprenticeship, and became a warehouseman in a printing-office; while engaged in which business he acquired, with the assistance of a fellow student in the university, a knowledge of Latin; and soon afterwards he began the study of the French language. He subsequently became a bookseller in one of the principal book-sellers of Edinburgh, and while holding that station he gave lessons occasionally in the evenings in mathematics.

In 1793 his increasing love for science, and a desire to have greater opportunities of cultivating it, led him to resign his employment in the city, which he had already been induced to do. He was appointed as mathematical assistant to the, so-called, Volunteer Artillery, of which he was appointed captain, and the mathematical exercises of his regiment were held at Perth. He married soon afterwards, and during the vacations he regularly visited Edinburgh, where his talents procured him an introduction to the distinguished scientific men of that city.

Mr. Wallace continued to fulfil the duties of his appointment at Perth during nine years; but in 1803 he was invited to offer himself as a candidate for the post of a mathematical master in the city of Edinburgh. The post of mathematical master had then been established, and the prizes for the purpose the plan of a small observatory was furnished by Dr. Robinson, of Oxford; and Mr. Wallace, who was appointed to deliver the lectures there, attended the detail of the construction. Such instruments were provided as sufficed for the object proposed; and it may be said that the establishment of a course of astronomy at the college has contributed materially to the efficiency of the college, and has been a powerful agency in the defeat of the opposition of the university of Edinburgh.

In the following year the death of Professor Playfair and the appointment of Mr. (Sir John) Leslie to succeed him in the chair of Natural Philosophy at Edinburgh, left a vacancy in the chair of Mathematics; and Mr. Wallace, whose highest ambition had always been to obtain a professorship in a Scottish university, immediately became a candidate for the post. He was elected, after a severe contest, by a majority of the votes, and he held the appointment to the last. A year later, when, on account of ill health, he resigned it. On this occasion the university conferred on him the honorary title of Doctor of Laws, and he received from government a pension in consideration of his attainments in science, as well as of his services in the Military College and at the University of Edinburgh.

Mr. Wallace died at Edinburgh, respected and regretted, on the 29th of April, 1843, and consequently in the 75th year of his age, after an illness which for several years had prevented him from entering into society. He had been a Fellow of the Royal Astronomical Society from the time of its formation; he was a Fellow of the Royal Society of Edinburgh; a corresponding member of the Institution of Civil Engineers; an honorary member of the Cambridge Philosophical Society; and, a few weeks before his death, he was elected an honorary member of the Royal Institution of Great Britain. In 1786 he presented to the Royal Society of Edinburgh his first paper, which was entitled *Geometrical Porisms, with Examples of their Applications to the Solution of Problems*; it contains some new and peremptory propositions, investigated according to the method of the ancient geometers, and affords proof of considerable inventive power. About the same time he contributed the article *Porism* to the third edition of the *Encyclopedia Britannica*.

In 1805 he presented to the Royal Society of Edinburgh a paper containing a new method of expressing the co-efficients in the development of the formula which represents the rectification of an ellipse. He had observed that when the time at which he gave to the ellipse a new curved line, and apparently Mr. Wallace had not seen them. Six years afterwards he presented to the same society a third paper, entitled *New Series for the Quadrature of the Conic Sections, and the Calculation of the Logarithms of a Number*. The remarkable formula for the rectification of circular arcs and the. sectors of equilateral hyperbolae, and for computing logarithms. In 1828 he presented a paper on the *Investigation of Formulae for the Logarithms of Two Numbers, which lies from one another*, and in 1831 one entitled *Account of the Invention of the Pantograph, and A Description of the
In 1754, he was appointed to the command of the squadron destined to co-operate with the expedition of Colonel Clive [Clive, Robert, Lord, P. C.] in the East Indies; and soon after his arrival in that country he received his Majesty's commis-
sion appointing him the Commander-in-Chief of the English squadron. The
first object of the expedition was the reduction of Fort Geriah, which was held by a piratical
prince, who had for many years annoyed the English trade in the East Indies. This service was performed by Admiral
Wason on the 17th of December, 1756, to the joy and gratification of the wives and children of this prince, who had become his
prisoner, was marked by the most courteous humanity. In the
attack made by Colonel Clive on Chandernagore, a place of
great strength, and very rich in treasure, he was so
awarded the small fleet of only three ships of the line destined to
co-operate with the land-forces. The French had prepared to
resist him by sinking several large vessels in the river below
the fort; but the admiral having found a safe passage by
carefully sounding as he approached, directed so severe a fire
upon the enemy's defences, that, seconded by Colonel Clive's
batteries on the shore, the place capitulated in less than three
hours (24th of March, 1757). By the capture of this force
a large number of prisoners, one hundred and eighty-three
pieces of cannon, and a considerable booty fell into the hands
of the English. With this exploit he may be said to have
ended his admiral's short but successful career; on the 16th of August
1757, he fell a victim to that unhonorable climate. His
death was severely felt by his companions in arms, by whom he was
adored. He had been for several years in the service of
the East India Company, and during the passage of the
successive modifications of the kingdom, and in the displacement
of the habitants, he had been very active. He had
received the title of Baronet, in 1763, is
Water PLANTAIN. [A1smaze, P. C.]
WATSON, CHARLES, VICE-ADMIRAL, was born in
the year 1714, and was the son of the Rev. Dr. Watson,
Princedale, Paras, in the county of Lanca-
ter. His military education was begun at an early age,
but not nine years of age enabled him to follow the inclination
he had already manifested of entering the naval pro-
fession. His skill and bravery soon procured him promotion;
and in February, 1738, he was commissioned captain of the Garland
frigate, and, in 1744, he was transferred to the Dragon of 60 guns,
under Admiral Matthews, on the Mediterranean station.
In that command his services were required on several
important occasions, and were most successfully attended with success.
He was afterwards sent by his admiral to Cadiz, with orders
to cruize off that harbour for a certain time, afterwards to pro-
ced to Lisbon, and from thence to England. After the
expiration of those orders he proceeded to Cadiz to inspect the making of many rich prizes,
he ventured to disobey them on receiving intelligence that
the enemy's fleet was preparing for sea at Toulon; and,
according to a commission from the 3rd of March, 1763,
gg, under Admiral Matthews, on the Mediterranean station.

WAX 704

WAX was formerly indispensable in metal-casting, though when and how it was first used is wholly unknown. It may have been used for the models of solid casts even in the earliest periods of modelling, but that the process was not yet confined to wax casting which was a later invention, and which will presently be described; though of an art so entirely practical, no description can convey more than a general idea.

In doing the same work at different ages give various directions for the preparation of the wax to be used. Vasari, who doth not mention that he used in his own time, recommends the admixture of a little tallow, turpentine, and pitch, with the common yellow ochre of varying quantities. The tallow renders it more soluble and fluid, the turpentine more adhesive, and the pitch colours it, and assists it in hardening after the operation is complete: it may also be coloured with a little red ochre in powder, which must be mixed with the wax in its liquid state. It may be made of colour in the same way. A French mixture is—to one hundred pounds of yellow wax, ten pounds of turpentine, ten of pitch, and ten of hops. Card, which probably would be similar in its properties to the mixture described by Vasari. When the wax is melted, great care must be taken that it does not boil, or it cannot be required when cold. M. Fichet, in his 'Art du Moulager en Plâtre,' of which there is an abstract in Panekoucke's 'Encyclopédie Méthodique,' gives the following formula for founder's wax—to four of wax, mix one of tallow, and a little pitch together. The admixture of these which when melted together are fluid and manageable. This will probably be the composition used by J. B. Keller and Girardon in preparing the mould for Girardon's equestrian statue of Louis XIV. In all cases it is now preferred, as wax is a compound material and can be cut to the shape required. Several other mixtures are and are probably employed by different sculptors; the above however were those employed in France and Italy in the great ages of founding, when the wax method was generally in use. We may now proceed to describe the methods of its application.

André Verrochio, a celebrated sculptor of the fifteenth century [VERROCHIO, P. C.], is said by Vasari to have been one of the first among the moderns to introduce whitewax which would be taken from life, or, in Vasari's words, to bring the practice into general use—"ele fu do' primo e beniscisse a metterlo in uso" (ed. 1568). These casts he made in wax and in plaster; and some writers have spoken of him as the inventor of moulding from the human figure, and others even as the inventor of casting in plaster; neither of which is said nor could have been intended to be conveyed by Vasari. Many arts have been known, and occasionally practiced, before they have been applied to the ordinary uses to which they were well adapted. There is in Florence still preserved in the cathedral a cast thus formed from the head of Brunelleschi, which Verrocchio has remarked, must have been taken when Verrochio was only fourteen years of age. And with regard to casting in plaster, if metal casts were made long before the time of Verrocchio, it is more than probable that plaster casts were made also. The first distinct use of chamber casts in modern times was Andrea Pisano [PISANO, P. C. P. S., p. 426], who modelled the gates of the Battistero of St. John at Florence, which were cast by some Venetian founders in 1350. These gates were previously known as the equestrian statue of a bronze crucifix to Pope Clement V. (1305-1314) at Avignon, which must have been about 120 years before Verrocchio was born. This crucifix is represented as having been of excellent workmanship; it must have been fashioned consequently by an artist or artists well acquainted both with mould-making and with casting, and the idea therefore that either art can have been ever completed until so late a period is absurd. Verrocchio is quite untenable. The fact of bringing casts from Venice to cast the gates of the Battistero of St. John does not so much show that Florence was without good metal-founders, as that Venice had obtained reputation of its art, sufficient to give rise to the opinion of this class. William Austen, a celebrated English founder, was anterior to Verrocchio. [AUSTEN, WILLIAM, P. C. S.] Bell-casting, which was practised throughout the middle ages, is a form of casting only the end of an art that its whole process in its process is of quite a different character from the modelling of works of imaginative art. However, at whatever period and by whatever process the early Italians first prepared their moulds, it is evident that they used wax, and that the most probable consequence used-wax in the preparation of the model for the casting. The antiquity of the Greek and Romans also probably used wax for the same purposes. There are few ancient monuments which do not contain portions of casts, and the survival of them is the equestrian statue of Marcus Aurelius before the Capitol at Rome. This monument is hollow, and was cast in two parts and probably the ancient method was not very different from that described by Vasari; some ancient works were cast solid. The Greek and Romans also probably used wax in casting statues of objects in fact the Greeks and Romans were more or less familiar with almost every method and concomitance known to the modern sculptor. Müller, 'Handbuch der Archäologie der Kunst,' Messmer, 'Technik der Kunst.'

It is generally allowed that the method of casting in modern times was Girardon's colossal statue of Louis XIV, cast by J. B. Keller in the Place Vendôme at Paris until 1752. After Girardon had completed it the monument was destroyed by the French and replaced by the present one. The monument is said to have been 66,000 lbs. and, its height, including the bronze pedestal, 21 feet. This enormous mass of metal required to be cast. The preparation of the model and mould was on the following plan:—When the model of the statue was finished, a safe mould of plaster and brick dust was made from it, in many parts. [MODELLING, P. C. S.] Each of these parts, being marked and numbered and removed from the model, was then oiled, and carefully filled on the inner side to a certain thickness, an inch or two, with the modelling-wax already described; the thickness depending upon the height or position of the parts being the thickest, for the metal is destined to fill exactly the space occupied by the wax. When all the parts of the mould were thus prepared, the whole was again put together. The mould was then placed, with a certain amount of clay to support it firmly in each direction; the lowest parts of the mould being first placed, and the joints of the wax of the various contiguous parts being filled in, and the piece carefully smoothed; the next end of the mould was then proceeded. When the whole was put together, it was bound on the exterior with strong bars of iron attached to the extremities of the bars of the interior framework. The mould is now a hollow shell, with a thick coating of wax all over it. The interior, the whole being kept together by iron supports, inside and outside. The next step is to fill this hollow shell, through an aperture left at the top, with a composition of plaster and sand, which is allowed to harden. The plaster body is termed in English a core (in some books written corps), by the French modigli, by the Germans kern, and with some writers the oima. Air-vents must be made in the shell before the casting of the core.

When the core is fixed, the original mould or shell is taken off, and a wax model of the statue appears to the eye. The sculptor now examines his wax model, and improves it where there is occasion and repairs or makes good all imperfections. When it is perfectly finished, the preparation for the founding commences. Over this wax statue a new fire-proof mould is made of plaster, brick dust or sand, cow-hair, and horse-dung, and sometimes very fine ashes. This composition, used at first as a fine liquid plaster, is put on in many coats with a brush, and care must be taken that every particle of wax is covered with the finer plaster: each coat is allowed to dry before the next is put on. The plaster is then carefully dried and be gradually made of a corner mixture. When this new shell or mould is of a sufficient thickness and is properly strengthened by iron bars, a coal fire must be kindled round it and be kept burning until the whole of the wax is burnt out, proper vents being made for its escape. This burning out of the wax is a very tedious and difficult process, lasting sometimes as much as four or even six weeks. (Stilt, Elisenda in Attacchi, Stiglmayr, p. 484.) Vasari, in his 'Introduzione,' e. xii., says the only way of knowing whether the wax is all out is to carefully weigh the quantity of wax that you put in the first place upon the mould, and then to weigh what you get out. The mould afterwards and to see that they nearly tally. If any wax is left in, there is danger of the mould bursting, independent of the hard uninteresting process of coating the wax. If the quantity of metal required to be melted was accurately ascertained. The great difficulty and long process of melting out the wax was the cause of what is called the wax method. By giving casting metal to the clay and sand modelling as its substitute has been generally established. Until 1824 Stiglmyser used the wax method; from that time the clay method. The largest single cast by Stiglmyser does not amount to more than half the weight of this enormous cast by Keller: it is however now
When the wax is at length melted out, the mould must be strengthened by brickwork, and the whole pit must be closely filled with sand and made water-tight; the mould is then abandoned and is divided in its course into three smaller channels or ducts which lead to three openings in the now hollow mould, which is buried in the earth a little below the furnace. The wax which is poured into moulds taken from the face itself would be the mere resemblance of death, for they would be without eyes and otherwise void of expression. They were probably cast from moulds taken from models, though such masks may have been used in the construction of the models.

Pliny (xxxvi. 9), speaking of the corrupt taste which prevailed among the Romans in his own time, regrets the good old customs of their ancestors. He says, 'Now all men think more of the material in which their likenesses are made, than of the art or the resemblance. The effigies they leave behind them are rather images of their wealth than of their persons. Thus it is that noble art decays and perish. With our ancestors it was very different; their halls were not filled with either strange images of brass or of stone, but with the lively portraits of themselves and of their forefathers, in wax, exact similitudes.' From this it appears therefore that the Romans loved their ancestors not as image of themselves made, to be handed down to their posterity. Many writers notice and praise the custom. Vitarus Maximus (v. 8), alludes to the advantages of the practice by virtue of example. It is said that at a banquet, during the time of the Roman Republic, some could make them but those who had themselves or whose ancestors had borne some curule magistracy. Cicero speaks of the right of handing down your image to posterity.

The number of ancient sculptors who have been known is considerable. To these we may add the names of some of the learned antiquaries who have adorned the greatest care. And when any other person of the same family diet, they are carried also in the funeral procession, with a body added to the bust, that the representation may be just, even with regard to size. They are dressed likewise in the habits that belong to the ranks which they severally filled when they were alive. If they were consuls or praetors, in a gown bordered with purple; if censors, in a purple robe; and if they triumphed or obtained any similar honour, in a vest embroidered with gold. Thus apparelled they are drawn along in chariots preceded by the rods and axes, and other ensigns of their former dignity. And when they arrive at the place where they are to stand, of ivory; and then exhibit the noblest object that can be offered to a youthful mind warred with the love of virtue and of glory. For who can behold without emotion the forms of so many illustrious men of former living, as if they were standing together in his presence? Or what spectacle can be conceived more great and striking? The person also that is pointed to harkens, when he has exhausted all the praises of the deceased, turns his discourse to the rest, whose images are before him; and, beginning with the most antient of them, recounts the fortunes and the exploits of every one in turn. By this method, which removes continually the remembrance of men celebrated for their virtue, the fame of every great and noble action becomes immortal; and the glory of these by whose services their country has been benefited is retained.

This wax-modelling has continued apparently from the time of the Romans until the present day. In the middle ages it was used for the casting of certain monuments in marble in art in his time, and doubtless the vulgar technical language of artists would have been unintelligible to the great majority of his readers, and artists themselves probably of one part of Italy. He calls Orsino as a wax-modeller the most ingenious of those of another part: it is more than probable that Vasiari had the difficult task of inventing a great portion of his terminology: he has been followed by all subsequent writers.

It remains to treat of that department of wax-modelling termed ceralastic. Under this term is comprehendetion moulding and casting in wax, though not in the manner already described. The art of casting in wax from nature was, according to Pliny (Hist. Nat. xxxvi. 44), invented by Lyctius-tratus, of Sicyon, the brother of Lyssippus, about 300 B.C., who, he says, first of all men took plaster moulds from the face and made wax effigies of them. In his time it became eventually very common, and especially among the Romans. It is however very unlikely that the many treasured wax portraits we read of in ancient writers were made from moulds taken from their face itself; that would be the mere resemblance of death, for they would be without eyes and otherwise void of expression. They were probably cast from moulds taken from models, though such masks may have been used in the construction of the models.
...of his escape. Orsino made, under the direction of Verrocchio, three wax images of Lorenzo of the size of life. The frameworks or skeletons of these figures were made of wood and cane, and the heads, hands, and feet were cast in wax, of coarser compositions, and then furnished with hair and glass eyes, and painted in oil-colours to the exact imitation of life; and were draped in clothes which had been worn by Lorenzo; to give the dressers a fixed character. These figures were altogether successful, says Vasari, that they appeared to be living. One of them was placed in the church of the Monache di Chiarito, in the Via di San Gallo; another in the Servizio; and a third in the church of Santa Maria degli Angeli at Assisi. In this Servizio church were many other wax figures by Orsino, all of which were marked with an O, in which was an R, and above it a cross; but they have all long since perished. Vasari adds that few works of later wax-modellers were to be compared with those of Orsino, and complains that the art had declined. A few years however after the death of Vasari, Jacopo Vivoti distinguished himself by a model on slate, in coloured wax, of Michelangelo's Last Judgment in the Sixtine Chapel. It was engraved by Ambroso Brambilla, and a particular description of it was published in Rome in 1590—'Dedicata sopra la mille milizie di di Bartolo di Meo di stucata con colori, scolpita in pietra nera, da Jacopo Vivoti.'

Two centuries after Verrocchio, and one after Vasari, this art was used usefully and with the utmost skill applied by Giacomo Giglio Zummo, and Francesco Zuccari, in 1666, in the preparations of anatomical models and pathological examples. Zummo obtained the European celebrity for his two groups of figures representing the stages of embalming and the different effects of the plague. He modelled also an anatomical head at Paris, which is described in the Mémoires of the French Academy of Sciences, of 1701, the year of his death. Zummo, P. C.

The first collection of anatomical preparations which was made for the purposes of science is that of the Institute of Bologna, established by Benedict XIV. It was commenced under the direction of Erode Lelli, and the preparations were made by Giovanni Manzolino of Bologna and his wife Anna Morandi Manzolini. Manzolini died at Bologna in 1755, aged 55. There are some of his models in London and in many other cities of Europe. Anna Manzolini obtained still greater celebrity than her husband: she executed all or the greater part of the obstetric models in the Stanza Ostetricia of the Institute which were prepared under the direction of Dr. Antonio Galli. She also gave public lectures on anatomy in Bologna, illustrating her discourse by appropriate models. She died in 1774, aged 57. (Crespil, Felicina Pittricce, where there are portraits of both the Manzolini.)

There is still more extensive and remarkable collection of wax anatomical models in the Museum of Natural History at Florence: it was established by the Grand-Duke Leopoldo, and the models are numerous and of good workmanship by various artists, but the principal contributors to its treasures were Felice Fontana and Clemente Sunini. The works of the earlier modellers in wax are set apart in a chamber by themselves; here are some of the models of Zummo, among which is one showing the whole anatomy of the human head, similar probably to the one made at Paris.

The Musée Dupuytren at Paris is celebrated for its morbid collection; it is perhaps the richest pathological collection in the world. It was purchased by the University of Paris, of the heirs of M. Dupuytren, the celebrated anatomist. Most of the principal cities of Europe have now their collections, and many universities are numerous. The Museum of University College, London, contains many excellent specimens by the late Mr. William Tulas.

In this department of modelling none but the purest wax is considered, and even the most perfect work must yield the wax in the final substance of the work. Different modellers use different compositions; and some allowance must be made for hot and cold weather, as what would be well adapted for summer work may be quite ineligible for winter. It is therefore necessary that each modeller should use simply wax and a small proportion of Venetian turpentine; other wax, resin, common turpentine, and a little olive-oil; and at least two-thirds of the whole composition.

It is seldom if ever used pure, as in all objects to be modelled white or some colour must predominate: for instance in modelling the brain, white in powder must be mixed in the composition, and the same respect must be had with regard to the predominant colour of every object to be modelled.

No strict rules can be given for the process of modelling, as each modeller will soon acquire methods of his own, and generally will commence by taking from some object the peculiar processes, imagining it to be detrimental to their interest. However, we may speak of general principles.

Nearly all wax models are cast from moulds, and the casts only then finished. But some modellers use wax as a pigment, and moulds are generally taken from the objects themselves, either in plaster of Paris or in a composition of bees'-wax, Burgundian pitch, and Venice turpentine, with a very small quantity of water, but a large quantity of oil, which may be either linseed, olive or linen-oil. These preparations, even when cold, if properly mixed, which must be learnt by experience, the mould is elastic or flexible; and if made thin, when cut on the edges can be peeled off the cast in pieces without any danger to the cast: in taking moulds in plaster of Paris, the object moulded must sometimes be destroyed to render the mould available. Round objects must be moulded in two or more parts. Sometimes when the object is cast in the mould, the mould must be destroyed before the cast can be removed, and in destroying the mould there is danger of destroying the cast also; the elastic mould therefore has great advantages in such cases over the plaster mould. When only one vision of a face is to be used, and it is only slightly convex, the plaster mould is quite sufficient, except the object itself, as the brain, presents a very uneven and delicate surface. In these cases the object must be cast in a box of soft wax, the mould must be moist with water, but not absolutely wet, or the water would injure the very delicate surface, which occurs in some pathological cases: the mould may be moistened with a little of any absorbent substance, not oil, but most in a dish of water, when it will soon absorb sufficient moisture for the purpose. The mould must not be oiled when any delicate work is to be done, as the oil will dissolve the surface of the wax, and thus perhaps counteract the principal aim of the cast. The wax-composition mould must be slightly touched with a soft hair-foil or with oil, to enable it to peel away afterwards without the slightest danger to the cast: being of a perfect smooth surface, the small quantity of oil it retains is immaterial.

When the cast is made, and what they call backed up (that is, strengthened with a coarser composition within), the process of painting commences; but all effects cannot be given by mere colour, some morbid deposits and effects require to be expressed by adding wax of the proper colour with a hair-pencil or other tool. The colouring is done from the natural object represented, with fine hair-pencil, or occasionally tinted with turpentine and tempered with a little wax; simple water is also sometimes used as the colouring vehicle. When the colouring is finished, the whole is covered with mastic varnish. In cases where the most minute morbid effects are to be shown of a distinct substance from the healthy texture, different coloured wax should be used in casting the healthy and diseased portions, and the parts may be corrected by modelling. The same principle should be observed in the representation of objects of natural history, as in preparing anatomical models; but fruit, which is generally in full or high relief, will require piece-moulds, that is, to be moulded in several pieces, which is done half or part at a time. Flowers are not all entirely cast, they are prepared from leaves of coloured wax made expressly for the purpose. These leaves are cut the required shape; they then, with the necessary colour and a hair-pencil, receive their local tints; and are finally joined and fastened into the required figure. Insects are modelled by combining the two processes. In moulding objects with hair or delicate raised parts, a little oil must be carefully put over the parts, unless they are protected. Dry firm objects may be modelled without oil; the plaster must be removed as soon as it is set. It remains yet to speak of the mode of making images. These likewise are made in various ways; but the essential process is, in moulding the object, the wax is first modelled, and when this is done, the wax is then dried up and filled up, or the object be modelled. The materials may be cast in any proportion of wax with a little wax. The wax is solid, as for example, is used for objects which must be modelled as perfectly as possible, and which cannot be cut through. This method however involves a considerable waste of time and materials. A more efficient method is to make wax models and cast a mould from it. The mould is then used, and very little wax is lost. After the mould is made, it is a simple matter to cast the object. The method is most suitable for nature casts, and for objects which can be cast and modelled. It is also very suitable for objects which are to be modelled in this manner:—Let a thin block be fashioned in a mould or otherwise, of coarse paper pulp and size; when dry it must be coloured all over with flesh-tint, the local colours being put on, a higher degree than is natural, as the colours of...
the checks, lips, and eyebrows; the whole then may be covered with wax, which must be poured over it two or three times, until the surface is well covered; its regularity may be secured by rubbing the corners of the wax and stringing it to run by means of a hot iron or burner (called cautery by the ancients) which must be hold near it until the whole has a uniform surface. The colour originally painted on the paper black, but the hair, the eyes, and a few local touches to finish it. Marks may be also dipped in wax, or the wax may be put on with a hair-tool, if the mask be kept warm; or a wax cast may be made, and the model slung hereon. There are however other methods of modelling wax figures, but no method can be properly explained by a verbal description; such mechanical processes must be witnessed to be understood. Modellers have made figures which would scarcely convey a sufficient notion to one wholly ignorant, and those well acquainted with the art have no need of such directions; for this reason this article has been limited to mere general principles, which is as much as the general reader can require or understand.

Many wax preparations of all kinds are of course made from more models made by the artist; and many preparations in museums, which appear to be wax, are painted plaster of Paris. Sculptors also are in the habit of making wax models of small objects in the round, or for bas-reliefs to be cast in metal. The wax used in the manufacture of the German and Dr. Webbs, the Swiss, and many American modellers use modelled clay models made of: the same wax is used as is required for casts. (Modelling, P. C. S.) Medals and small bronzes are generally modelled in wax. Impressions from seals, engravers, and maps, are taken with a powder; the wax which is prepared with a little powdered sugar-candy, turpentine, and lamp-blank, after being melted, is preserved in small cakes. These cakes when wanted are softened by repeated pressure of the fingers, and are then compressed into or upon the seals or cameos, previously wetted, from which the impressions may be required.

WEBSTER, NOAH, LL.D., was born at West Hartford, in Connecticut, U. S., 20th of October, 1758, and was descended from John Webster, who, having been one of the original emigrants from Massachusetts by whom the colony of Connecticut was founded, was afterwards governor of the state in the year 1654. Noah Webster entered Yale College in 1774; in 1777 he was withdrawn for a time from his studies by joining the military service under the command of his father, who was a captain in the Alarm List, during Burgoyne's expedition from Canada; but notwithstanding his interruption he took his degree with great distinction the following year. He was called to the bar in 1781; but, instead of following the profession of law, he engaged in that of education. He was connected with William Eliot, president of the now-celebrated institute of the English Grammar,' published at Hartford in 1783, was the first of a number of elementary works produced by him, all of which were well received and were generally adopted by the schools. His Grammar had previously possessed. He also however took a leading part in the discussion of the political questions of the time, both by his 'Sketches of American Policy,' published in 1774, and his other publications on the subjects of federalism, and by the establishment in 1789 of a daily paper in New York, which still subsists under the name of 'Commercial Advertiser and New York Spectator.' In 1798 he removed to New Haven, where he spent the remainder of his life. His great work, and that which has chiefly made his name known in this country, his 'New and complete Dictionary of the English language,' was begun in 1807, and the first edition was published in 1828. This work, which had been since several times reprinted, the last edition, we believe, being that of New Haven, 1841, in 2 vols. 4to., is a performance of great labour and care, and is perhaps more precise in its explanations than any of our other English dictionaries. Its etymological portion however is more ingenuous and scantly than really learned or profound. Dr. Webster, whose degree of LL.D. we believe bestowed upon him after the publication of his dictionary, died at New Haven on the 27th of May, 1843.

(Memoir in Gentlemen's Magazine for August 1843.)

WERNER, JOHANNES, a German mathematician and astronomer, was born in the first half of the year 1468. Nothing apparently is known of his life, except that, when he was twenty-five years of age, he went to Italy, where he made some astronomical observations; and he is said to have made a series of observations on the comet which appeared in the month of April in the year 1500; from observations which he made on the positions of Regulus, a Virgin, and a Libra, compared with those which had been assigned to the stars by Ptolemy and Albategnius, he determined the precession of the equinoxes to be 70 minutes of a degree in 100 years, a quantity much too small: and he found the obliquity of the ecliptic to be 25° 28'. In the year 1512, he published 'Annotationes in the First Book of Ptolemy's Geography,' in which he endeavoured to explain an obscure passage concerning the projection of the celestial sphere on a plane surface; and it deserves to be remarked in that in the same year the English printer, John Trevisa, published the method of determining geographical longitudes by the angular distance of the moon from some star: he recommends, for making the observation, the cross-staff or fore-staff, a rule instrument which is now commonly known by his name. In 1522 he published at Nürnberg, in 4to., his 'Opus Mathematica,' in which is contained a treat on comi:es: he also published a work on Trigonometry, in five books, containing a great number of astronomical and geographical problems.

Werner wrote explanations of the construction and use of meteorological instruments; and it is said that he collected a number of observations with a view of discovering from them rules for determining the changes which take place in the atmosphere. He executed a machine in which the movements of the planets, and planets were represented conformably to the Ptolemaic system; and was employed on 'The Movement of the English Skies.' He died in the year 1524.

HISTORIA ASTRONOMIAI, by Weidner; Histoire de l'Astronomie Moderne, by Delambre.

WESTERN PORT. [WALES, NEW SOUTH, P. C.] WETHEIRELLIA, a genus of fossil fruits from Shapley and Bowesbank.

WHITSTONE, GEORGE, a voluminous writer of prose and verse, lived in the latter half of the sixteenth century. Both the place and time of his birth are unknown; but he was admitted kindred with Sergeant Fleetwood, the recorder of London. His history was that of a succession of misadventures. He began by wasting his patrimony in seeking a place at court: he then served abroad as a soldier, and was an eye-witness to the fall of Sir Philip Sidney at Zutphen: he was next an unsuccessful farmer; afterwards he sailed with the abortive expedition of Gilbert to Newfoundland; and, finally, returning to England, he appears to have been chiefly occupied during the remainder of his life in literary labours which he had previously practised occasionally, and now attempted with indifferent success as a means of subsistence. He is now chiefly known as having been the author of the rule play (or romance) 'Patience or the Embattled Cuckold', which had previously possessed. He also however took a leading part in the discussion of the political questions of the time, both by his 'Sketches of American Policy,' published in 1774, and his other publications on the subjects of federalism, and by the establishment in 1789 of a daily paper in New York, which still subsists under the name of the 'Commercial Advertiser and New York Spectator.' In 1798 he removed to New Haven, where he spent the remainder of his life. His great work, and that which has chiefly made his name known in this country, his 'New and complete Dictionary of the English language,' was begun in 1807, and the first edition was published in 1828. This work, which had been since several times reprinted, the last edition, we believe, being that of New Haven, 1841, in 2 vols. 4to., is a performance of great labour and care, and is perhaps more precise in its explanations than any of our other English dictionaries. Its etymological portion however is more ingenuous and scantly than really learned or profound. Dr. Webster, whose degree of LL.D. we believe bestowed upon him after the publication of his dictionary, died at New Haven on the 27th of May, 1843.

in the last-mentioned year he set up a second Spanish Journal.
the 18th century, and the work was quarterly, and continued for about three years. Other separate works follow, both in Spanish and English; those among the latter that attracted most attention being his Practical and Internal Evidence against Catholicae, 1826, and again 1826: 'The Poor Man's Preservative against Popery,' 1825, several times reprinted; 'Second Travels of an Irish Gentleman in search of a Religion,' (in answer to Moore's well-known work) 2 vols. 12mo, Dublin, 1835. He was also an occasional contributor to the Quarterly Review, to the London Review, established in 1829 (of which he was the editor for the size of the work), to the Athenaeum, and Westminster Review, to the Journal of Education (in an early number of which he wrote one article on the State of Education in Spain), to the Dublin University Review, and to the Quarterly Review.

He resided occasionally at Oxford and Dublin as well as in London; and in 1830 he settled in Liverpool, where he continued till his death, which took place on the 30th of May, 1841. He left a son, who in 1840 was a major in the English army. Of White's writings probably those that will last the longest are the papers which have been published since his death under the title of The Life of the Reverend Joseph Blanco White, written by himself; with portions of his correspondence, edited by John Hamilton Thom, 3 vols. 8vo, London, 1845.

WHITE LIGHT is the name generally given to the light which comes directly from the sun, and which has not been decomposed by reflection in passing through a transparent prism; it is not, however, considered as a colour of light, being rather a union of all the differently coloured rays of which common light is composed.

A white light produced by mixing together 24 parts of saltpetre, 7 parts of flour of sulphur, and 2 parts of red arsenic, was used for the signals employed to render visible by night the stations by which the trigonometrical survey of France was conducted. This light was very bright, and could be seen by the naked eye in cloudy weather at distances exceeding 40 miles; but it has, since, been superseded for such purposes by other kinds of light. [Davison's Life of Captain William Frederick I., King of the Netherlands, Grand-Duke of Luxembourg, Prince of Orange Nassau, was born at the Hague on the 24th of August, 1773. His father, William, Count of Orange Nassau, Duke of Berg, Prussian Stadtholder, was descended from John the youngest brother of the great William I. of Orange, and died at Brunswick, April, 1801. His grandfather William IV., the first Hereditary Stadholder of the United Netherlands (from 1748 who died in 1751), had re-united the possessions of the four branches of the line of Nassau—Otho, Baden, Siegen, Dillenburg, and Dietz with his own branch, that of Dietz. His mother was Frederica Louisa Wilhelmina, daughter of Prince August of Anhalt-William of Prussia. In 1778 he made a journey to Germany, and passed some time at the court of his uncle Frederick William I. He afterwards studied for a time at Leyden.

So long as the war lasted, from the 1st of October, 1791, to Frederick Louisa Wilhelmina, daughter of Frederick William of Prussia, and, in conjunction with his brother Frederick, subsequently distinguished as a general, effected considerable improvements in the Dutch army; but many important actions of the Dutch army, occasioned by internal dissensions, the patriots, who had been put down in 1787 by a Prussian force, secretly intriguing against the house of Orange. Some months had been taken up in this enterprise; but on the 9th of February, 1793, the State Convention declared war against the Stadtholder. Hoping with the assistance of the patriots, to obtain possession of the rich provinces of Holland, Demarcois conquered Dutch Brabant, which was however recovered by the hereditary prince, who was commander-in-chief of the Dutch army, which was joined by a body of the allies, after the victory of Neerwinden on the 16th of March, which had been gained over Daumont by the 3rd of March. The hereditary prince then hindered the French army of the North from penetrating into West Flanders; but on the 13th of September he was attacked in his position between Menin and Dunkirk by the army of the Duke of Brunswick, and forced to retreat. He was the most gallant resistance, in which his brother Prince Frederick, who commanded the right wing, was wounded, he was obliged to retreat behind the Schelde. Soon after this hereditary prince took up his residence in Bruges, and the Austrian army, driven the enemy beyond the Sambre: but in the great battle of the 16th of June, 1794, the French having taken Charleroi by storm and defeated the prince's left wing at Fleurus, he was forced to retreat to Oudenburg, and from thence to Coburg, to retreat. The Austrians retreated, before Pichegru and Jourdan, behind the Meuse; and the hereditary prince, with his weakened army, had no alternative but to cover the republic in connection with the army of the Duke of York. But the fortresses fell, and the frost enabled the enemy to pass the Waal on the ice, so that Pichegru entered Utrecht on the 17th of January, 1795. The party of the patriots favoured the enemy, and the stadtholder was unable to save the republic, forsaken by its allies. His sons had resigned their commands on the 16th of January, and William V., with his family and a few faithful friends, embarked at Scheveningen on the 15th and 16th of April, 1795; where the prince was assigned him as his residence. His two sons returned to the Continent to arm a body of Dutch emigrants, at the expense of England, which had been dispersed again after the conclusion of the peace of Rastatt. Prince Frederick therefore accepted the Austrian service, and died at Padua on the 6th of January, 1799.

The hereditary prince then went with his family to Berlin, where he expected a favourable change in his position, from the diplomatic influence of the Prussian court, then in alliance with France. He acquired some estates in the vicinity of Posen and in Silesia, and when his father made over to him, on the 29th of August, 1807, his property in Germany allotted to him by the Reccess of the Empire (Fulda, Corvai, Dortmund, Weingarten, and other places), he took up his residence in Fulda, where, in the place of the inefficient university, he established a lyceum, and appropriated the revenues of two suppressed convents to the foundation of a national hospital. After the death of his father he assumed the government of his Nassau hereditary dominions; but as he declined joining the German Confederation of the Rhine, he lost the sovereignty of the possessions of the house of Orange, which were obtained by his relations of Nassau-Uningen and Weilburg, and Murat, Grand-Duke of Berg; while Weingarten fell to the Duke of Berg, and the field-marshall Maximilian, who became a prince of war in consequence of the capitulation concluded by Miihlendorf; he was allowed however to reside with his consort in Prussia. Napoleon declared that he, as well as the prince of Nassau, had forfeited his dominions; and Fulda was forced already, on the 27th of October, to do homage to the French Emperor. Corvi, Dortmund, and the county of Spiegelberg were incorporated in 1807 with the kingdom of Westphalia and the grand-duchy of Berg. Even the domains reserved to him, in the act of the Confederation, were taken possession of by Berg and Wurttemberg; Bavaria did not do so, and the other princes of the Confederation acquiesced in this night, and the not surplus of the revenue. William had come in the mean time with his consort and family to Danzig. When the war approached the Vistula, he desired to return to Berlin, but only his own interests, and a desire to save his dominions, induced him to remain at Friedland. When the army of the field-marshall Gneisenau was victorious, he devoted himself to literary pursuits. In the war between France and Austria in 1805, William, with the friend of his youth and constant companion, Fugel, joined the army of the Archduke Charles, and led a volunteer corps of English volunteers in Wagram. He then returned to Berlin, and in 1814 obtained the rank of Austrian field-marshall. Meanwhile, especially after the battle of Leipzig in 1813, influential men such as Hohenlohe, v. d. Lvne, Limpurg-Stein, Hopl, Died, Jengo,
and others, were exerting themselves at Amsterdam, the Hague, Rotterdam, Zotte, and other places, to effect the restoration of the house of Orange. William was at that time in England to concert measures with the Dutch government for the support of the Dutch cause. When the officers at Leipsic approached the frontiers of Holland, the inhabitants of Amsterdam rose on the 15th and 16th of November, and on the 17th the Hague declared war. This was unexpected; but France still had great resources; the formidable barrier of the Rhine was not yet passed, and when that decisive step should have been taken it might be followed by irreparable disaster to the French empire. Some differences with France had diminished the influence of Holland; a creation of alarm in Paris, while the allies hailed it with joy, as an earnest of further success, and were encouraged to prosecute their military operations with increased vigour. When Captain Wauzz was sent from the Hague to the head-quarters of the allies at Frankfort, he met at Munich, on the 22nd of November, the Prussian general Bulow, who being informed of what had passed in Holland, observed that this insurrection would be as advantageous to the allies as a successful campaign; and the same general, a few days afterwards, assured Baron Van Zuylen, Van Nyevelt, and Count Bylandt, sent from Holland on a diplomatic mission, that the Rhine would never venture to think of crossing the Rhine before the return of spring. What might have been the consequence if the allies had waited till the spring, instead of carrying the war in winter against the Rhine, the Rhine had remained so much time to Napoleon, may be inferred from what actually happened in the wonderful campaign on the banks of the Seine and the Marne in 1814, in which Bonaparte displayed all the extraordinary resources of his fertile genius.

As soon as William learnt what had passed, he embarked on the 28th of November, and landed at Scheveningen on the 29th. He was received with acclamations by the people of the Hague on the 30th, the towns of Amsterdam, where Kemper and Scholten, the commissioners of the provisional government, had issued on the 1st of December a proclamation, announcing ' Holland is free,' and 'William I. the sovereign Prince of this free country.' The prince gratefully assented, and declared that a constitution must guarantee the rights and liberties of the people, and secure them against all encroachments. Twenty-three fortresses were still in the hands of the French, who were encamped near Utrecht, but the army of the allies, and the volunteers, who were called to arms, occupied the country. William hastened the arming of the people, and appointed a commission of 200 commissioners, of which 60 were appointed on the 29th of March, 1814, by the deputies of the people, and then sworn to by the prince. He had already taken possession of his hereditary dominions in Germany, before the 30th of March, and had occupied the States of Belgium and Liege, together with the Seven United Provinces, should be formed into one kingdom, and on the 18th of March, 1815, the prince was proclaimed at the Hague as King of the Netherlands and Duke of Luxembourg. But he was obliged to cede to Prussia his hereditary possessions in Germany for Luxembourg, which after the 22nd of May, 1815, belonged to the German Confederation, and which he now raised in May to the rank of a grand-duchy.

The union of so many provinces, the inhabitants of which, though of the same origin, differed very much in manners, customs, and religious doctrines, made a change in the constitution necessary. A commission consisting of an equal number of Dutch and Belgians, was appointed to make such changes as were requisite. After the king had approved of this draft of a constitution, it was laid before the States-general and deputies from the southern provinces, and finally proclaimed on the 26th of August, 1814. In 1815 the king founded the military order of William, and in 1815, after the battle of Waterloo, the civil order of the Belgian Lion, and on the 31st of July, 1816, joined the Nassau family in the house of Nassau, of which all Christian slaves were to be restored to liberty.

In the interior of the kingdom, a want of harmony between the inhabitants manifested itself on several occasions, which, but for the moderation and firmness of the king, might even then have led to serious dissensions: the unbounded influence of the Roman Catholic clergy, even over the higher classes in Belgium; the mutual aversion of the Belgians and the Dutch, and the dissatisfaction of the lower classes with the court at Brussels; divisions in the northern provinces between the friends of the old republican system and those of the new or monarchical system, tended to produce discord, which was kept within bounds only by the prudence and firmness of the king, and the mild conciliatory principles of his government. In the foreign relations of the government, in the main, the alliance between the Dutch and the Prussians, the forces of which were united, and the possibility of opening a closer union was however caused by the marriage of Prince Frederick to the Princess Louisa, daughter of the King of Prussia, on the 21st of May, 1825.

The union with Holland and various commercial treaties with foreign powers had given an extraordinary impulse to the manufactures and commerce of Belgium, especially of the cities of Antwerp and Ghent, but the government could not succeed in blending the Dutch and the Belgians into one nation. Their mutual aversion was manifested with great sincerity in the church, in the army, and even in the assemblies of the States general. The intolerance of the Roman Catholic clergy, which, as was the case with the prieurs of the ancient order, the Jansenists, the bishops of Utrecht, Haarlem, and Davenport, who had taken the oath of allegiance to the king, and the prohibition of the French language in all judicial proceedings, created a great irritation in the country, and was afterwards passed as a law; but it was necessary to modify it in several points; and besides these important differences respecting religion and language, there were several financial points in which the interests of the northern and southern provinces clashed; and which, notwithstanding several very beneficial measures, could not hinder the final separation of the two parts of the kingdom.

The union of Belgium and Holland had subsisted for fifteen years. The cities, the manufactures, the commerce of Belgium, had attained the highest degree of prosperity, but nothing could conciliate the refractory spirit of the Belgians, with the phlegmatic character of the Dutch, nothing could conquer the aversion of the people of Brabant and Liege, founded on differences in manners, religion, and language, from Protestant Holland. The July Revolution of 1830 in France revived the old mutinous pride of the Belgian cities, and a rising of the mob in Brussel, on the 3rd of May, 1830, commenced the revolution which separated the northern and the southern provinces. In consequence of a second insurrection in Brussels, on the 20th and 28th of September, negotiations arose between the representatives of the Prince William, of the Prussians, and of the armed insurgents, conducted by foreign officers, which ended in the retreat of the Dutch. Meanwhile the king, yielding to the desire of a Belgian deputation of which this committee formed a part, consented to meet them on the 13th of September to discuss with them the question of a separate administration, and an alteration of the fundamental law. The two chambers were in favour of it, but the insurgents, supported from Paris by the Propaganda, contended for a total separation, which already existed in fact, when the five powers, Great Britain, France, Austria, Russia, and Prussia, imposed a cessation of arms on both nations, and, by the protocol of the 4th of November, 1830, recognised the independence of Belgium. This is not the place to inquire into the motives which induced four of the great powers, instead of exerting themselves to maintain and defend the bull-dog spirit, by which they had themselves erected as a security against the future encroachments of France, to unite with France in demolishing their own work. But justice requires us to acknowledge that the conduct of William I. on this great and trying occasion was such as was dictated by honour, good faith, and regard for the interest of all, and far from prejudicing the rights or legitimate interests of any government, it entitled him to the esteem and gratitude of all the cabinets of Europe.

King William protested, on the 12th of July, 1831, against the eighteen articles presented by the great powers, particularly against that which proclaimed the freedom of the Scheld, and promised to the Holland, with equal earnestness, the establishment of a law of nations of which all Christian slaves were to be restored to liberty.

In the interior of the kingdom, a want of harmony between the inhabitants manifested itself on several occasions, which, but
WILLIAM 710

men, crossed the Belgian frontier; Turnhout and other places were taken; one Belgian army was defeated near Hasselt on the 18th, and a second, near Lokeren on the 10th; and a French army advanced by forced marches, and the English and French ambassadors at the court of Brussels negotiated an armistice, according to which the Prince of Orange evacua-
ted the following day, the 15th, and his army retired to its post-
before the war. A treaty in twenty-four articles was then pro-
ounced by the London Conference, which was acceded to by
Belgium, but rejected by King William. Russia, Prussia, and
Austria had signed some articles, and France, though offered a
peace, a honourable one, but the clauses in the articles were to
be modified, but France and England had recourse to meas-
ures of coercion. England blockaded the coast of Holland, an
embargo was laid on the Dutch ships, and the caitled of Ant-
wragh was paid. By the 12th of December, after a memorable
siege by a French army of 70,000 men. This did not im-
mediately lead to peace between Holland and Belgium, but a
suspension of arms was effected on the 21st of May, 1833.

The London Conference resumed its difficult task; many
important questions remained to be settled: an interminable
series of protocols ensued; William did his utmost to delay
the conclusion of these negotiations, in hopes of some turn in
his favour, and hostilities between Holland and Belgium were
on the eve of recommencing at the end of 1833, and were pre-
vented only by the remonstrances of the Conference. At
length, induced chiefly by his financial embarrassments, Wil-
liam signed a treaty of peace on the 10th of February, 1834, signed
twenty-seven articles, modified to his disadvantage; and the
definitive treaty was concluded on the 19th of April, 1835, by
the plenipotentiaries of the Netherlands and Belgium, and of
the powers among whom.

But though Holland was now wholly separated from Belgium,
there was great excitement in the Dutch Chambers in 1833.
They hoped for favourable financial laws and judicial reforms;
instead of which proposals were laid an annual loan of
fifty-six millions of florins. The loan was rejected on the
20th of December, and the budget on the 23rd; a loan of
only six millions was granted, and the budget voted for six
months only. At the next meeting of the States-General, in
March, 1840, the king caused several modified projects of
law to be laid before them; in consequence of which the civil
list was fixed at one million and a half of florins; and it was
resolved to vote the budget for two years only instead of ten
as hitherto. But notwithstanding this endeavours of the
government to satisfy the people, the discontent with the
king and the ministers increased. The king's passion for the
Countess Henrietta d'Outremeu, a Roman Catholic lady, ex-
cited the general indignation of the people, so that he declared
on the 26th of March, 1840, that he renounced his projected
union with her. This affair, and the discovery of an extensive
conspiracy in Belgium, in which the Dutch appeared to be
concerned, and finally the financial difficulties of the state,
induced the king solemnly to resign the government on the 7th
of December, 1840, into the hands of the king's son William.
Under the name of Count of Nassau, with an immense private
fortune, he fixed his residence at Berlin, where, on the 17th
of February, 1841, he married the Countess d'Outremeu,
and took the title of Hertog van Oostenrijk. On the 21st of
November, 1843, he left his large property for his family, besides a gift of ten millions of florins
to the Dutch treasury.

(Baron de Kerferd, Du Royaume des Pays Bas, vol. iii. Svo., La Hague, 1834; Brockhaus, Conversations Lexicon, 1846; Mémoires tirés des papiers d'un homme d'état; Mr. Chad, Narrative of the Revolution in Holland, London, 1803.)

WILLIAMS, DANIEL, D.D., a Protestant Dissenting
minister of the Presbyterian denomination, was born
at Wrexham, in Denbighshire, in the year 1644. The
advantages of his early education were compensated by
the natural endowment of his mind, and by his diligence.
He was one of the first of the new generation who entered
the Christian ministry after the ejection of the Nonconformists
in 1662; and at the age of nineteen he was regularly admitted
as a minister. He was one of the most popular preachers in
several parts of England, though the times were so unsettled
that there was little prospect of his continuing his
labours without hazard. This circumstance, however, did
not prevent his remaining among his people; and, though
his talents and his prudence would have enabled him
to enter the church-establishment with a fair chance of
advancement. As, in these days, more religious liberty was
granted by Parliament, he removed his establishment from
England, and in 1690 Williams repaired to the soil-country, and unexpectedly

received an invitation to become chaplain to the Countess
of Meth, which he accepted. Some time afterwards he was
cited to appear in Dublin. Here he remained nearly twenty years, and filled
his station with great credit, being at the same time much
esteemed by the Irish Protestants in general. During his
residence in Ireland he had the management of a school
established for the purpose of for this did not meet with encouragement, which
proves that he was in advance of the age among his contemporaries in the practice of the art of poetry. In 1553, Dr. Williams became apprehensive respecting the safety of the Protestant succession, from the meanness of the prime minister, the Earl of Oxford; and he remonstrated on the subject with the pope and with the princes to whom he was in acquaintance. It happened, not long after, that a copy of a letter which Dr. Williams had written to his friends in Ireland on Lord Oxford's measures fell by accident into the hands of a bishop, who immediately sent it to the Duke of Northumberland, who, on his first sight of it, immediately took the letter to his lordship, who, already displeased with the doctor for the counsel which he had volunteered, now never forgave him. On the accession of George I. in 1714, he determined to give up London, and to return to the scene of his early youth, and to readmit to his majesty, at the head of the London dissenting clergy of the three denominations; and from this time it has been usual for this body to go to court on similar occasions, it being one of the bodies which are received on the throne, and by their committees in the royal closet. Dr. Williams's health had by this time visibly declined for a year or two, though he still continued the exercise of his ministry. At length, after a short attack of asthma, he died on the 26th of January 1716, in the seventy-third year of his age, and was buried in Bunhill Fields. In his funeral sermon, Dr. Evans, who had been his co-pastor for eleven years, ascribes to him a "copious invention, a penetrating judgment, a faithful memory, and vigorous affections, which were cultivated by much application to study." His moderation was shown by his desire for a comprehension of the Revolution, on condition of a free toleration to the dissenters of all parts of the town. His discourses and treatises extend to six volumes 8vo., and have been collected and published at different periods: the last volume consists of Latin versions of several of his treatises, translated for the benefit of foreigners, agreeably to the instructions of his will. He also directed that his treatise entitled 'The Vanity of Childhood and Youth' should be rendered into Welsh for the use of schools, and printed often for the benefit of the poor.

Dr. Williams bequeathed the bulk of his estate to benevolent and useful objects. Having provided for his widow, he left donations to the Society for the Reformation of Manners; for the education of youth in Dublin; for an itinerant preacher to the native Irish; to the poor of the Wood Street congregation in Dublin, and of that in Hand Alley in London; to the French refugees; to the poor of Shoreditch parish; to assist poor ministers and students; to several ministers' widows; to St. Thomas's Hospital; to the London workhouse; to the Society for promoting Christian Knowledge in Scotland; and he established medical charities in London, and for the maintenance of charity-schools in Wales. He sold left estates to the university of Glasgow, which at present furnishes six handsome exhibitions to students for the ministry amongst the poor. In 1717, he bequeathed all his library to his trustees. The last grand bequest in his will was four the establishment of a public library in London. For this purpose he had bought Dr. Bates's collection of books for between 500l. and 600l. to add to his own. He directed his trustees to erect a suitable building, the site for which was purchased by them in 1727, in Red-cross-street; and the library was opened in 1729. All persons may obtain admission on application to one of the trustees. Since the library was established, very considerable additions have been made to it by legacies, as well as by contributions in money and books. It contains upwards of 16,000 volumes; and in 1841 a new catalogue was made, in two volumes. The library contains treatises and sermons which had never been catalogued before.

Dr. Williams's library will be memorable in future time as the scene of preparation for many of those noble struggles for civil and religious rights, which have characterized the great social position which dissenters from the established church now enjoy. The large room in which the deliberations of the united ministers of the three denominations were carried on for weeks, is the object of much curiosity, and still remains. It is adorned with a magnificent collection of the portraits of the nonconformist fathers, and of their more immediate successors. It is well known however that the lapse of time has somewhat marred the beauty of several of the portraits, and that at least one of the three bodies, though still retaining its original name. So long as there was common ground of sympathy on which all could meet to redress common grievances, all things went on with harmonious success. The library was placed on both sides to be great and momentous, but they were not brought into question: other objects intervened, and the three denominations continued to be a political body aiming at a great social end, rather than a religious. They had scarcely had their efforts brought about the repeal of the Corporation and Test Acts when differences arose, and the want of religious sympathy in the sections of the body began to manifest itself. The three denominations, with the exception of the Unitarian members, who formed the great majority of the Presbyterian body, seceded from the three denominations on the 17th of March, 1836, and the Congregationalists, the Baptists, and the remaining orthodox Presbyterians are still known and recognized by the government as the 'Three Denominations,' whose meetings are now held in the Congregational Library, Blomfield Street.

(From Willams's Works: Calamy's Continuation; Bogue and Bennett's History of Dissenters; Congregational Magazine for 1836.)

WILSON, DR. THOMAS, a noted statesman and scholar of Queen Elizabeth's time, was the son of Thomas Wilson of Strebly, in Lincolnshire. He was educated at Eton and at King's College, Cambridge, and afterwards became tutor to the two sons of the Duke of St. Albans. He was a member of the Royal Society. He was appointedsuccessor to the Duke of St. Albans.

The Rule of通用art, containing the Art of Logic;" and in 1553, "The Art of Rhetoric." Both works were frequently reprinted in the course of the century, and both have received much commendation from modern critics; the latter in particular being held to give the author a title to be considered as the earliest critical writer in the English language. Full specimens of it are given by Warter. On the accession of Queen Mary, Wilson found it convenient to retire to the Continent. He took the degree of doctor of laws at Ferrara; but, on proceeding to Rome, he was apprehended by the Inquisition, and is said to have been put to the torture; the grounds of charge being said to have been found in the works he had published. On the death of pope Paul IV. (1556), the discontented populace of Rome broke open the prison of the Inquisition; and Wilson was one of those prisoners who then escaped. On Elizabeth's accession he returned to England, was immediately taken into the public service, and rose rapidly from place to place. He was at first minister of state, and master of St. Catherine's Hospital, and private secretary to the queen; in 1578 he was sent as an envoy to the Low Countries; and in 1577 he was appointed one of the secretaries of state, and afterwards became a dean of Durham. He died in 1593.

WILSON, ALEXANDER, was born at Paisley, in Scotland, July 6, 1786. His mother died when he was ten years of age, and his father, embarrassed with the charge of a young family, soon married again. In 1793, he was apprenticed to a weaver for three years, on the expiration of which he worked about four years as a journeyman weaver, and then abandoned the loom, and spent nearly three years as a pedlar. From an early age he had been cultivating a talent for poetry which he imagined himself to possess, and in his excursions for the sale of his wares endeavoured to procure subscriptions for a volume of his poems, but without success. The volume was never published, but verses and single poems were published in newspapers and separately. 'The Laurel disputed,' a poem on the respective merits of Ferguson and Ramsay, was reprinted before a literary society in Edinburgh, and published there in 1793, and in 1794, in Edinburgh, in a quarto book, with a portrait, from which is generally his 'Watty and Meg,' which some at first ascribed to Burns, to the no small gratitude of Wilson. His poetry however made no impression on his countrymen in general, and he resolved to emigrate to the United States of North America.

On the 14th of July, 1794, Alexander Wilson landed at Newastle, in the State of Delaware, with only a few shillings in pocket, and a Dissenter's almanac in his hand. He was employed for a few weeks by a copper-plate printer; he then resumed successively his former occupations of weaver and pedlar, but afterwards became a land-measurer, in order to obtain a livelihood, and ultimately turned printer and book-binder, and engaged in the publication of various works in the different places in Pennsylvania and New Jersey. At length, in 1802, he made a contract with the trustees of a...
school at Gray's Ferry, on the river Schuylkill, in the township of Kingess, about four miles from Philadelphia, and here he became acquainted with Mr. Bartram, the botanist and naturalist, whose gardens were always open to him, and whose conversation stimulated and improved the taste for natural history which his turn for observation and his rambling life had developed. Here too he became acquainted with Mr. Lawson, the engraver, who gave him instruction in drawing, particularly in the delineation of the human figure, but with little promise of becoming a draftsman, till Mr. Bartram proposed a trial of birds, in which he succeeded beyond the expectation of his friends; and from that time his whole life had nearly a right into play. Writing to a friend in Paisley, in June, 1825, he says, 'Close application to the duties of my profession, which I have pursued since Nov., 1796, has deeply injured my constitution; the more so, that my rambling disposition was the worst calculated of any one's in this world for the serious regularity of a teacher's life. I have had many pursuits since I left Scotland—mathematics, the German language, music, drawing, &c., and I now only wish to make a collection of our finest birds.' In October, 1804, Wilson, accompanied by two friends, set out on a pedestrian journey to the Falls of Niagara. They reached the Falls, and satisfied their curiosity, but were overtaken by the snows of winter on their return. One of his companions remained with his friends near the Cayuga lake, the other availed himself of a conveyance; but Wilson walked on with his gun and bundle, through trackless snows and uninhabited forests, over mountains and along dangerous rivers, and reached home at the beginning of December, after a journey of 1257 miles, of which he walked 47 the last day. All the time he could spare was now devoted to the examination of birds, and making drawings of them in colours. In 1806 Mr. Bradford, bookseller, of Philadelphia, being about to publish a new edition of Reeve's 'Cyclopaedia,' engaged Wilson as assistant editor. Soon afterwards he explained to Bradford his views of a large work on American ornithology, and the bookseller undertook the publication.

Wilson was ambitious in his devotion to his duties as assistant editor, while at the same time he prosecuted the great undertaking which had become the favourite object of his ambition with an enthusiasm which was characteristic of him. At length, in Sept., 1808, the first volume of the 'American Ornithology' was published. From the date of the first arrangement a prospectus had been put in circulation, in which the nature and intended execution of the work were specified, but no adequate idea had been formed of the book which was in preparation, and when the superfluous volume made its appearance the American public were alike astonished and delighted. It was in folio, with plates carefully engraved from Wilson's own drawings, coloured after nature, and with admirable letterpress descriptions; the price was 120 dollars. In the course of September, 1808, Wilson journeyed eastward and northward, and during the winter went through the southern States receiving his book and endeavouring to obtain subscribers. He visited in fact every town within 150 miles of the Atlantic coast, from the river St. Lawrence to St. Augustine in Florida. He received much praise, but got few subscribers. Wilson however was not depressed.

The second volume was published in 1810, and soon afterwards he set out for Pittsburg on a journey to New Orleans. From Pittsburg he descended the Ohio by himself in a skiff. He started on the 4th of February, and on the 17th of March moored his boat safely in Bear Grass Creek, at the rapids of the Ohio, after a voyage of 720 miles. His hands had suffered a good deal in rowing. He had made excursions from the banks of the river, as he proceeded, with his gun and drawing materials, in search of new species of birds, of which he made drawings and wrote descriptions. In doing this he shot 1700 birds and 700 ducks, and in the end himself. The other volumes of his work were brought out in succession, with astonishing rapidity and regularity; the number of his subscribers increased, and before his death included perhaps every royal personage in Europe. In 1812 he was elected a member of the American Philosophical Society. In 1818 he published the 7th volume. He had completed the pictorial materials for the 9th and 10th when he was carried off by an attack of dysentery in his forty-eighth year. He died August 23, 1813, at Philadelphia. The 9th and 10th volumes were completed and published in 1814 by Mr. George Ord, who had been his companion in many of his exploring expeditions. Mr. Ord supplied the letter-press descriptions for these two volumes, as well as a biography of Wilson in the 9th. Three supplemental volumes were afterwards supplied by Charles Lucy Bonaparte,folio, 1825-1828.

Wilson's pictorial representations of the birds are considered to be of great excellence. His descriptions are not only technically accurate, but exceedingly clear and graphic, in whatever relates to their motions and characteristic habits. It is a delightful book. The mind is so much absorbed with the images and scenes as to be hardly conscious of the act of reading.

Wilson was about five foot ten or eleven inches in height, handsome and vigorous, but rather slender. He was always distinguished by the neatness of his dress and appearance. He was a man of the strictest honesty and the most scrupulous regard for truth; social, affectionate, and benevolent, but somewhat irritable under contradiction and critical objection. He was never married.

(Memoir of Wilson, annexed to the American Ornithology, by Alexander Wilson and Charles Lucy Bonaparte, in Constable's Miscellany.)

WOLF-FISH. [Amphicthys, P. C. S.]

WOLF-BANE. [Acustemon, F. G. S.]

WOOD, DECOMPOSITION OF. [Timber, Preservation of.]

WOODSIA, a genus of ferns, having circular sori, with an infundibular extension, divided at the edges into numerous capillary segments.

W. liberis is one of the rarest of our British ferns; it is found in only two localities in Europe, one in Wales, and one on the Banks of the British river called the W. In Scotland it is found in several places, and in the blackest part of mountainous places. The fronds are elongated, the pinnae triangular, with deep lobes, the rhizome tufted. There are varieties of this species, which are by some writers considered as distinct species, but Mr. Babington thinks this division unnecessary.

XANTHIAN MARBLES. These interesting marbles, which will shortly be opened to the public in the apartments built expressly for them on the western side of the British Museum, are likely to form one of the most attractive portions of the British collection of antiquities. They consist of a large collection of sophranical marbles of various ages, which were first made known to the European public by Mr. (now Sir Charles) Fellows, who first performed the important task of collecting them in 1843. They were all found in or near Xanthus, the ancient capital of Lycia, a small country on the southern coast of Asia Minor. [A.MANOLI, P.C.S.] Xanthus is an ancient town, and was built on the river of the same name (now Etchon-Chid), at the distance of seventy stadia, or nine or ten miles, from its mouth. The first mention of the Xanthians in history is in the first book of Herodotus, c. 176, where he describes the capture and destruction of their city, in the middle of the sixth century B.C., by Harpagus, the general of Cyrus. Herodotus says that the Xanthians, after burning their wives and children, were all destroyed by the soldiers of Harpagus. He continues, that those who inhabited the city in his time were all foreigners except eighty families, who were absent on a foreign expedition. He says nothing of their monuments. Five centuries later nearly a similar fate happened to them when they were besieged by Brutus: the city was destroyed, and only one hundred and fifty Xanthians were left, says Plutarch, and this against their will. Many of the monumental buildings of Xanthus must have perished. In this second destruction: it was however again restored, as is evident from the Greek inscriptions and the state of its ruins when discovered by Sir C. Fellows. These different conquests, will in some words, explain for the various characters of its monuments and inscriptions.

The origin of the Xanthian collection of marbles may be briefly described. In 1839 the attention of men of letters and artists, both in England and in other countries, was called to the subject by the following publication and its illustrations:—"A Journal written during an Excursion in Asia Minor," by Charles Fellows, 1838. In this account the remains of Xanthus were represented as of a very early age, and portions of its walls as Cyclopean. The ruins were in many places covered with inscriptions, many in a perfect state, but in an unknown language, which Mr. Fellows resolved, by a resemblance of the language he found at the Corinthian tombs of the early Persians. Many of the ruins, the rock tombs, were described as resembling those of Persepolis. The ruins consist of walls, temples, tombs, triumpahal arches, and a theatre, and are situated on a flat, richly cultivated hill. The remains of the city are stately, and upon beautiful hills, some crowned with rocks, others rising perpendicularly from the river, which is seen winding its way down from the woody uplands, while beyond, in the extreme distance, are the snowy mountains in which it rises. These picturesque ruins are covered with sculptures, and their elegant designs, says Mr. Fellows, evince the talent of the Greeks: and the highly poetical subjects of the bas-reliefs, some of them blending, in one figure, the forms of many, probably to describe its attributes, are also of Greek character.

The account of these ruins attracted more attention than their discoverer expected, and soon after the publication of his first journal, he, in 1840, a second journey to Lycia, by Sir Charles Fellows, to give a more satisfactory account of his discoveries. The results of this journey appeared in "An Account of Discoveries in Lycia, being a Journal kept during a second Excursion in Asia Minor," by Charles Fellows.

In consequence of the more accurate and satisfactory account in this work, and the representations of various persons to the Government ofthe British Museum, and the facilities of transporting some of these Xanthian relicks to England and Great Britain in particular, after them from further destruction, an expedition was fitted out in the autumn of 1841 for the purpose, and permission being obtained, the collection of the Marbles was deposited in the British Museum in 1842. In 1843 a second expedition was sent out, and the remains of the Marbles arrived towards the end of the following year. The Marbles now consist of some hundred and twenty fragments of other monuments, and the whole will be shortly opened to the public, partly arranged in the Museum as they were originally found by Sir C. Fellows. The tombs have been named, from their sculptures, the Winged-chariot Tomb, the Harpy Tomb, the Chimera Tomb, and the Lion Tomb: the first two were found entire, the others in fragments. These two entire tombs, to which it is contemplated to reconstruct, are the principal marbles of the Xanthian collection. One, the Winged-chariot Tomb, is a sarcophagus, entirely of white marble, stand at the foot of a hill. The marble being a fine worked, the polish has greatly assisted in its preservation from the effect of the atmosphere. The roof is somewhat grey, and the fractures of the lower parts are tinged with the red tint which white marble assumes after long exposure to the weather, and in places with yellow blended with brown. On the top or hoy's mane is a hunting scene; some figures are running, others are on horseback galloping, with spears in their hand, and mantles blown by the wind, chasing a stag and a wild boar, which has turned to attack the pursuer. All the figures, though small, are, in the opinion of Sir C. Fellows, well formed and finished. On each of the sloping sides of the roof are two stones projecting about a foot, as found on all these tombs, but which upon this are carved into lions' heads crowching on their paws. Upon one side of the roof is a group, in which a warrior carrying a shield is seen cutting the base of a column. In the set of stepping into his chariot, which is of the early simple form, with wheels of four spokes only; the driver is leaning forward, with his arms stretched out, holding the reins and a whip or goad; four beautifully formed horses, prancing in various attitudes, are attached to the chariot. A nearly similar chariot and horses are carved on the other side of the roof, varying only in the attitudes of the figures. In the upper panels at the ends or gables are traces of small carved figures. On one side of the tomb stands a chariot, given in "A Journal of 1838," under two lines of Lycian characters, is a group of figures, which, beginning from the left, is thus described by Sir C. Fellows:—"A finely formed figure in a simple robe, his hands folded before him, and with a head of bushy hair, stands as if in attendance behind the chair or clavel seated on the central figure, who, clothed in rich folded drapery, with short hair, sits in the attitude of a judge, with an arm somewhat raised; before him stand two persons; the first is mutilated, but appears similar to the second, who has long bushy hair, crowned round the head, and looking like a wig; his attitude is that of a councellor pleading for the others; the loose robe falls gracefully from one shoulder, and is thrown over, so as almost to conceal one arm: two other figures, differing only in having the hair shorter and the arms hanging down, stand apparently waiting the decision of the judge, and complete the well-knit group." The word or name Pafisa is inscribed over the judge.

At the end, on a larger scale, are two figures of warriors, clothed with short mantles, and girdles of armour round their loins, above petticoats reaching nearly down to their knees. The back-ground of this bas-relief contains a long but, from mutilation, illegible inscription: it is copied in the Second Journal. On the opposite side of the tomb are two other figures of the same size; one, clothed in a loose robe, stands in a commanding attitude fronting the spectator, with an arm raised over the head of a naked figure, also standing. (Second Journal, p. 166, where both ends are engraved.)

On the second side of the tomb, under a single line of inscription, is an animated battle-scene: men on horses are fighting with others on foot; all have helmets, and those on foot have shields; some fight naked, others with a loose shirt or blouse descending below the thighs, and confined by a belt round the waist. The horse of the principal figure is ornamented with, and the rider has, a kind of armour to protect his legs.

The groups upon the two sides of the tomb are three feet six inches high by nine feet in length. The height of the whole tomb, including the base, is about twenty feet, or twice its width at the side when exposed; it has been broken open in all its parts. In style of execution it is the imitation of a wooden structure.

Upon the other or Harpy tomb, a high square pedestal which was near the tomb at Xanthus, are two curious bas-reliefs. (First Journal, p. 232, and Second Journal, p. 170. Vol. II.—4 Y
Many of these fragments of sculpture built into the walls of the acropolises are now in the Museum; they are also engraved on certain of the larger coins of the Lycian kings. As these figures are the chariots and the costume of the figures of some pieces are of an early age. The forelocks of the horses are tied in a peculiar way, similar to those of some horses in a bas-relief at Persepolis, which has been noticed by Mr. Daniel Sharpe, who holds the opinion that, by its style, the head is meant to be a pig; he also has loose drapery, and a stick resting against his shoulder and held in his hand; before him is the figure of a warrior delivering up his armour: in one hand he holds the helmet, in the other a shield. On the middle of the east side an old man is also seated in a chair, likewise with a long stick resting against his shoulder; in one hand, which is raised, he holds what appears to be a small bird towards his face, and before him a child or youth is presenting a cock; behind the child are figures with one hand raised, and a dog looking back up into the face of the figure: behind the chair of the old man are two female figures, one holding a child on her side somewhat below the seat, the other holding likewise some small object up before her face. On each extremity of the west side is seated a female in a chair, looking much like the two to one of these ancient scenes: woman in her hand, towards the middle, is more than half way up, and on a very small scale, a cow suckling its calf; beneath the cow and calf is an opening in the tomb, which may have been intended as the doorway into the tomb; next to the opening, and looking towards the other female seated in the chair, are three females standing, similarly attired in loose drapery and in similar attitudes, each holding some small object down by their sides, and with the other hand raising a cup or other object to the mouth; the seated figure on this side is similarly occupied. They have all low head-dresses; some the tiara; others wreaths or plaited hair with tresses hanging down behind. The figures are about three feet high, and be four compartments, about nine feet in length, form the dress of the persons, and are elevated about twenty feet above the ground upon a square pedestal of grey stone, and roofed with two flat stones of a similar material; the bas-reliefs are in white marble. There is no inscription on this tomb, which, from the figures carrying off the children, is supposed to allude to the story of Pandarus, King of Lycia. These figures are the legendary daughters of Pandarus: Homer, Odyssey, b. xliii. (Second Journal, p. 170.)

Close to this tomb was another similar tomb of the same district, here called Glycy by the Lycian; covered with Lycian marble. These Xanthian tombs extend over several miles of country.

The walls of the city are extensive and massive; Cyclopean is blended with Greek architecture; and several gateways with massive columns have been left still existing. In the acropolises many beautifully wrought marbles are built in as materials, without any regard to their sculpture. Lions, warriors, chariots, and horses are to be traced in many fragments, and birds like our game-cocks fighting. On the site of a small temple Mr. C. Fellowes found a frieze about ten or twelve feet long and one in width, representing a series of fifteen small dancing figures with flags draping. There were the ruins of many, in all temples in the neighborhood: Sir C. Fellowes considered the sculptures to be Greek. He says however of the ruins generally—Xanthus possesses some of the earliest architectural sculpture in Asia Minor, and it is connected with the most beautiful of its monuments, and illustrated by the description of Xanthus at the Parthenon. These sculptures to which I refer must be the work of the sixth or seventh century before the Christian era, but I have not seen an instance of these remains which have been descriptive of the rebuilding of the walls; and yet the decidedly modern works of a later people are used as materials in repairing the walls around the back of the city and upper parts. Many of these are Greek inscriptions, with names common among the Romans. The whole of the sculpture is Greek, fine, bold, and simple, bequeathing an early age of that people. No sign whatever is seen of the works of the Byzantine.
one of the pediments also shows that the Persian is the de-
feated, not the victorious party. That the monument is a com-
manding one can be observed by any one living at a part of
the town.

If this monument can be explained into a monument to
Harpagus, it must have been executed about 150 years after
the event commemorated; for though it may be hazardous to
fix the date of a work from the state of its execution, in a
handling, there is not much rashness in pronouncing when it was
not executed; and there is evidence in the design and work-
manship in this monument to show that it was not executed
until Franz, the celebrated king of Portugal, had already
beneath, or certainly not earlier than about 400 a.c., and
probably considerably later. After a certain time, when mastery
has superseded hesitation in design and unskilfulness of execu-
tion, the masons left off working in the old manner, and
clidean stiffness of attitude are replaced by freedom and fac-
cility, with everywhere the evidence of a skilful expression
of what was required. The journeysmen also by whom such
marbles are long accustomed to the easy mastery of the
models of a finished age, themselves acquire peculiar
characteristics of execution; touches given with little trouble,
but by which much is accomplished; grown old in mastery,
they become careless and free to extravagance in their execution.
All these evidences are in this Xanthian mon-
ument; the draperies of the mutilated female statues com-
bine the highest mastery in design with the utmost facility of execu-
tion. If these evidences are so strong, they are not
Before the works above quoted on these marbles, Sir C.
Cotgrave has published a pamphlet entitled "The Xanthian
Marbles, their acquisition and transmission to England," 1824.
Their inscriptions are already known to the literati, but it
may be well here to give a specimen of their freshness and
beauty on a stele or column described as erected to a son
of Harpagus, who was a celebrated boxer. (Kunstblatt,
1845, p. 306.)

XANTHIDUIM. Some of the minute organic bodies in
the chalk and flint of England are referred to this genus of
Insufusoria, but perhaps without sufficient reason. (Manet.)

XAVIER, FRANCIS, SAINT, was born at the castle of
Xavier, in Navarre, on 7th April, 1506. His father, Don
John de Jasso, was counselor to the King of
Navarre, and his mother, Maria Azpilcueta, was heiress of the
two illustrious houses of Azpilcueta and Xavier. Francis
was the youngest of a large family of children, the eldest of
whom bore the surname of Azpilcueta, and the others that of
Xavier. Under the paternal roof he received all the advan-
tages which the age and situation of the family could
command. He was early marked out for a public career, and,
when he was only seven years of age, he was sent to the
monastery of St. Martin de Brive, where, after a short stay,
he proceeded to the kingdom of Travancore, where, in one month,
he was established in his novitiate, and where, in the course of
four years, he acquired such a degree of proficiency in the
Arabic language, that he was appointed to teach the
language to the students of the college of St. Francis, at
Travancore. He then passed to the college of St. Francis,
and, after a short stay in the latter, was appointed to
the bishopric of Goa, and there, in the course of a year,
he was created a cardinal. He was then appointed to
the see of Macao, and, after a short stay in that see,
was promoted to the see of Canton.

In 1552, he joined Ignatius Loyola at Rome, where he
actively assisted him in the furtherance of his great design of
associating a body of devoted men for the special service of
the Church of Rome. While in that city, he exercised the
functions of the ministry in the church of St. Lawrence
in Damaso, and attracted to it large multitudes by his zeal and
talents. Among them was a Portuguese of the name of
Goves, who had been sent to Rome on a mission of import-
ance by King John III. In his communications with the
king he had expressed himself in terms of high commendation
of the new society which had lately sprung up under Loyola;
and had suggested the propriety of selecting missionaries from
among the Portuguese colonies in Asia. He had urged the need of
a Portuguese colony in Asia. Influenced by these representations,
the king dispatched an order to his ambassador at Rome to
obtain six members of that society, who might be willing to
devote themselves to the conversion of the Portuguese
inhabitants of the East. The king was induced to accept of
the society of six Portuguese, and the names of the six were
Thomas de Maia, Gaspar de Vitoria, and the brothers
Hippolito and Puitalo, who were selected by Loyola. As
he was about to set out on his journey to Lisbon, Bobadilla
was suddenly called back by the king, on account of his
brother's illness, and the commission of his chief to become his substitute. Having previously ob-
tained the benediction of the Pope, Paul III., on himself and
his holy enterprise, he left Rome in company with the Portugu-
ees, and arrived at Lisbon about the same time as the
ambassador. As the road to Lisbon was long and tedious. As they passed through

XAVIER, Simon, was born at Salsette, where he

influence of his death, he declined the offer of the
ambassador, and the king was inclined to accept of the
proposition. The king was, however, induced to take the
monument at Lisbon, and relations, whom it was probable he might never again see.

In the excess however of his zeal for the prosecution of the
purpose to which he had devoted himself, he declined avail-
ing himself of the offer of the Portuguese magnates. He
had promised, however, that he would show no transient pleasure of a lost farwell might leave too lasting an
impression of melancholy on his sacred enterprise.

Xavier and his companions arrived at Lisbon towards the
end of June. After spending a short time, and leaving his
companions of the Jesuit Society, he set sail on 4th April, 1541, Xavier embarked on board a vessel, which car-
ried Don Martin Alphonso de Souza, governor of the Indies,
but unaccompanied by Rodriguez, who had been persuaded by
the king to remain in Portugal. After a few months, they arrived at the coast of Mozambique in Africa,
where they wintered, and at Goa, the Portuguese seat of
government in the East Indies, on 5th May, 1542.

On landing, the first visit of Xavier was to the hospital;
his next to his spiritual superior, the bishop of Goa, to whom he
presented the brief of Paul III., and implored his sanction
and blessing on his missionary enterprise. He had scarcely
commenced it, when he made the painful discovery that the
disciplines in which he was anxious to instruct the infidels,
were openly contradicted by the life and example of the
greater part of the Christian residents in Goa. To their
spiritual reformations, he directed all his attention; and,
going from street to street, with a bell in his hand, he
summoned every inhabitant to send him his children and slaves,
in order that they might receive Christian instruction.
Having secured his intentions, he directed to his superiors
his ministrations to expose the prevailing vices, and to present
the remedies which religion affords. From the Christians, his
zeal extended itself to the infidels, whose temples he caused to be
destroyed, and churches to be erected on their site.
His labours were speedily rewarded by Goa by a marked reforma-
tion among the inhabitants. After a residence of six months
in that town, he left it to visit the coast of the pearl fishery,
which extends from Cape Comorin to the Isle of Man.
There he found that, although a large proportion of fishers
had been baptized in the Christian faith, they had, for want of
instruction, retained the vices and superstitions of heathendom.
In order to give them that instruction, he laboured for some
time most assiduously in acquiring the Malabar language.
His first preaching among them was attended with extra-
ordinary success. After a stay of fifteen months on this
station, he returned to Goa for the purpose of procuring assis-
tants to his work; with them he returned, in 1544, to the
fishers of the pearl coast, and left several of them in different
parts of his work. In 1547, he proceeded to the kingdom of Travancore, where, in one month,
he was in the hospital of Goa, where he devoted himself to the service of the sick, without neglecting the principal object of his mission,
which was to instruct the people. A large number of con-
verts from among Mohammedans, Jews, and others, was the
result of his labours. While at Malacca he was joined by three
other Jesuit missionaries, whom Ignatius Loyola had sent
to cooperate with him. In company with them, on the 1st
January, 1546, he set sail for the islands of Banda, and, it is
said, became the happy instrument of the conversion of
the entire crew of the vessel which carried him. From hence
he proceeded to the island of Ambon, where he baptized a large
number of the inhabitants; he then preached the Gospel in
other islands, and, having made a considerable stay in the
Moluccas, he broke up for the coast of Java, by which he
reached the island of Celebes. On this voyage, he reached
the island of Balipoo, where he had planted the faith: he arrived at
Malacca in 1547. After leaving Malacca he made some stay
in Java, and then proceeded to the coast of Sumatra, and then
over to the island of Ceylon, where he converted the King
of Candy and several of his subjects; on the 30th May, 1548, he
returned to Goa. At Malacca, he had met with a Japanese
name, named Auger, who, on his return, accompanied him
for some time. Having baptized Auger, with two of his domestics, and given

Y 2
him the more Christian name of Paul of the Holy Faith, he set out with him from Goa on this difficult enterprise. After making a short stay at Malacca, he embarked on board a Chinese vessel, and arrived on the 15th August, 1549, at Cangoxima, in the kingdom of Sancian, in Japan. [JAPAN, P. C.] The chief difficulty he had to overcome in this expedition was his ignorance of the Japanese language. Xavier, during his voyage, had, by means of his convert, acquired some little knowledge of it, which was increased by his stay of forty days at Cangoxima, and which was sufficient to enable him to translate into it the Apostles' creed without an exposition. The little progress, however, which he made in it proved a serious hindrance to his success, as appears from the letters he sent home. Through his conversion, he was introduced to the king of Sancian, who gave him a favourable reception, but declined hearing him on the subject of religion. In the hope of finding a more suitable field for his missionary excursions, he left Sancian, and proceeded to Frindo, the capital of another small kingdom. He was there allowed freely to exercise his ministry, and numerous conversions were the fruits of it: in that city he baptized more infidels, in twenty days, than he had done at Cangoxima in a whole year. Encouraged by this success, he left these converts under the care of one of the Jesuits who had accompanied him, and set out for Macao, the capital of the whole empire and the residence of his ecclesiastical chief. [JAPAN, P. C.] On his way thither he visited Amanoguchi, the principal town of the kingdom of Naugato, where he was allowed to preach in public and before the king and his court, but with little success: after a month's stay in that city, he continued his journey towards Macao. Though it was the depth of winter, and the rugged roads, difficult at all times, were now rendered almost impassable by drifts of snow and mountain torrents, yet, thinly clad and barefoot, he pushed on onwards, resigned and cheerful. He arrived at Macao in February, 1551, having been about two months on his journey. There his most necessary and wearisome garments proved a subject of offence to the inhabitants; accustomed to the gorgeous and pompous ceremonial of their own religion, the priests, whose influence was paramount in that city, could not see in this new ambassador of the God of High. Though rejected with contumely, Xavier did not abandon his holy purpose, but returned to Amanoguchi, where he provided himself with a rich suit and a retinue of attendants, and thus attired presented himself before the court. This harmless device procured the desired effect; he obtained the protection of the king, and preached with so much success, that he baptized three thousand persons in that city. These converts he left to the care of some Jesuits who had been the companions of his journey; and, accompanied by two Japanese Christians, who, rather than renounce the consolations of the religion he had taught them, had cheerfully suffered the confiscation of their property, he departed from Amanoguchi, in September, 1551, and, on the 30th of November following, embarked to return to India, having remained in Japan two years and four months. This mission was, for upwards of a hundred years after the death of Xavier, regarded with such reverence by the Japanese as to be called the 'Xavier's mission.' [Missons, P. C., vol. xv., p. 267.] On his voyage he made some stay at Malacca, chiefly for the purpose of concerting measures with the governor of that place for the prosecution of a mission to China. A serious obstacle to it was the law which forbids strangers, on the severest penalties, to enter that country. To remove it, it was agreed between Xavier and the governor of Malacca that an embassy should be sent in the name of the King of Portugal to establish a commercial treaty, and that Xavier should join it. On his return, however, to Malacca, he found the new governor, who had arrived there during his absence, determined to proceed to Macao, and, after many unavailing entreaties to persuade his consequence, he was obliged to embark alone for his intended mission on board a Portuguese vessel bound for the island of Sancian, near Macao, in China, a place where the Chinese were permitted to traffic with the Portuguese merchants. On arriving there, the merchants of Sancian endeavoured to dissuade him from his design of prosecuting his journey farther, and strongly represented to him the danger. Xavier however was not to be deterred; he provided himself with an interpreter, and entered into an agreement with a Chinese merchant to land him by night on some part of that coast. It was by this means that he was encountered by the Portuguese residents of Sancian, who feared that this attempt to infringe the laws might be visited upon them by the vengeance of the Chinese authorities. While thus disappointed in his first venture, he certainly had no reason to complain of his sufferings, which were most acute, were aggravated by the inattention and want of skill of those around him; in the midst of them however he displayed a cheerful countenance and a holy resignation. He arrived December 2, 1552. His remains were brought over to Malacca on the 22nd of March, 1558, where they were received with the greatest honour; they were afterwards transferred to Goa, and deposited in the principal chapel of the church of Paul; on the 16th of March, 1554. The memory of Francis Xavier was consecrated by a ceremony known in the church of Rome by the name of Beatification, by the Pope Paul V., in 1619, and he was canonized as a Saint by Gregory XV. in 1622. In 1747, John V. King of Portugal, obtained a 'benedict' of Benedict XIV., which conferred on him the title of patron and protector of the East Indies. His festival is observed by the Church of Rome on 3rd of December. The works of Francis Xavier have been translated into many languages, and are numerous, and not sufficiently known in England; Pan Cyclo. art. 'Missions;' the statement made in it that Xavier was canonized by Urban VIII. is erroneous, but it is true that this pope first gave him the title of the 'Patron of the Indies.' The life of St. Francis Xavier has also been written in Latin, by Turcinus, Rome, 1594; in Italian, by Orlando, Barròli, and Maffei; and in French, by Boisbour, a work which was translated into English by Dryden in 1688. XULIONOSPONTINII, one of the fossil fruits of Shropshire. Bowerbank.) XYLOPHIA, a genus of plants belonging to the natural order Annonaceae. It has 6 petals and numerous stamens; the calyx from 8- to 10-lobed, the segments ovate, concolorous, and acute; the ovaries distinct and numerous; the ovules ascending in one row attached to the central axis; the carpels free, ovate, compressed, indihecious, stalked, and from 1- to 4-seeded. X. longifolia is a tree 70 feet high, the leaves oblong, acuminate, silky and shining beneath, revolute at the margin, pubescent on the upper surface especially by the base. The flowers are small, the hypanthium ovate, ovate, compressed, indihecious, stalked, and from 1- to 4-seeded. X. glabra is a tree native of Jamaica and Barbadoes. The branches are smooth and scarcely dotted; the leaves oblong, ovate, and smooth, on very short stalks. The peduncles are slender, solitary or in clusters of three. The calyx is smooth, trihedral, with very obtuse lobes; the carpels smooth. The flower-buds are oblong, pebbaceous on the outside. The wood, bark, and berries of this tree have an agreeable bitter taste, similar to that of the lime. All the species of this genus require a stove-heat. They grow best in sandy loam and peat, and ripened cuttings will root in sand under a glass-house in moderate heat. (Don, Gardner's Dictionary; Lindley, Flora Medica.)

YORK, CUSTOM OF. [Wife, P. C.]
ZAMITES, a genus of fossil Cycadeoidea from the coalitic, wealden, and cretaceous formations (Prel.) synonymously with Mantellia and Brogniart.

It is a plant of Africa, at the western extremity of the Gulf of Aden, not far from the Straits of Bab-el-mandeb. It is situated in 17° 49' N. lat. and 43° E. long. The harbour is small and shallow, so that even small vessels cannot come within half a mile from the beach. The town is enclosed by walls now in ruins. The houses, with the exception of eight or ten, which are built of stone, are either of wood or reeds, or of both these materials. Some guns planted on the wall from the land side are a sufficient protection against the Somalils, who inhabit the surrounding country. The population is stated not to exceed five hundred souls. All families are engaged in trade, Zeela being one of the harbours by which the inhabitants of Harran carry on a commercial intercourse with Arabia. Three caislas arrive annually from the interior, especially from Harran. They bring to Zeela slaves, both male and female, large quantities of gum and myrrh, coffee, jowari, ghee, and ostrich feathers, also some grain, especially millet, wheat, and beans. Most of these articles are sent to Mocha, and at present probably also to Aden. In return they take back blue and white coarse cloths, Indian piece goods, European prints, silks, silk thread, shawls, red cotton yarn called shumah, beads, zine, copper-plate, frankincense, and Austrian dollars. Zeela is subject to the Pasha of Egypt, by whose authority the Deliah of Mocha nominates the Zeela, who pays an annual tribute of 300 dollars, and keeps a garrison of seventy soldiers, armed in part with matchlocks.

ZAMUN, SHAH. [SHAM DIN, P. C.]

ZINC, Medical Properties of. In the purely metallic state, zinc produces no effect on the human system, but its combination with oxygen is sufficient to invest it with considerable power over the organs, both those with which it comes into direct contact and some remote ones, especially the nervous centres. Its local action is that of an irritant, astringent, and desiccative, while its remote action is that of a tonic and antispasmodic. By disinfecting properties, it is more powerful than either of those forms of the sulphate or acetate, unless it meets with acids in the stomach. In this way it is rarely employed. It is for its remote effects, when taken in small long-continued doses, that it is valued. While it has the properties common to all the metallic antispasmodics, it is distinguished by its power of restraining inordinate action of the nervous system; being calming and soothing. The brain and the function of sensation appear to feel less of its influence than the spinal cord. Hence the nerves of motion, and the functions of the circulation and respiration, are chiefly acted upon; it produces its effects slowly, but they quickly disappear when given in such doses as can be safely administered. The long-continued use of it seems to produce a dryness and induration of the frame, which if carried to excess is dangerous, but the lesser degree of which is in all probability the source of the utility of this medicine, by diminishing the mobility of the body system, irregularities in the circulation, and sudden congestion of blood, being the immediate causes of attacks of epilepsy and hysteria, the diseases which are most benefited by one of zinc.

In spasmodic affections of the chest, as asthma, angina pectoris, and palpitation of the chest, when these do not proceed from organic derangements, oxide of zinc is often serviceable. In the action of the stomach, the cramps of the stomach to which habitual drunkards are subject, it is very useful.

Irrap礁 oxide of zinc is called tarry. It is sometimes used in medicine as an antispasmodic, astringent, and disinfectant, and to heal ulcers and cracks in the skin. It is also used as an ointment. Pure oxide of zinc forms an ointment of much value where a mild astringent is needed, especially in the chronic cases of ulcers.

Carbontate of zinc when impure is termed calamine; this after being subjected to diverse processes, is called prepared calamine. The only use made of it is to form an ointment, which is most useful as an application to burns, excoriations, and superficial ulceration.

Sulphate of zinc in small doses a very valuable astringent, tonic, and antispasmodic; in larger doses it is a very certain and speedily acting emetic; and in very large doses it is poisonous. It is the practice of doctors to use it internally, as it is not so apt to inflame the stomach as tartrated antimony: but the stomach-pump is preferable to either. The tonic effects are best seen in affections of the mucous membranes. In the coughing fits of aged persons, and the extreme defluxions on the chest after influenza, sulphate of zinc affords a valuable remedy: it must be given in small doses, as the sudden suppression of the secretion may cause inflammation. The use of the solution as an injection requires the same caution.

Acetate of zinc is possessed of nearly similar properties, but in a weaker degree; and as an injection, seems in some cases entitled to a preference.

Chloride of zinc, called also butter of zinc, is a powerful escharotic or caustic; this action results from its strong affinity for albumen and gelatine, which principles it abstracts from the burns and ulcers, of the living tissue, and forms an eschar. Its powers in this way have been taken advantage of to destroy parts affected with malignant diseases, such as cancer and lupus, and to remove nevi, material, or mother-marks. In some of these it is to be recollected that they are very superficial. Deep-seated cancer of glands can scarcely be removed by it, but other forms are often successfully treated by it. (Walshe On Cancer, p. 219.)

Cyanide or cyanuret of zinc is a powerful antispasmodic and tonic. No medicine is so potent in allaying irritability of the stomach attended with great debility. The dose must be small and often repeated. Valerianate of zinc has lately been much recommended as a remedy against tic-douloureux and other nervous affections. Where the patients can tolerate the repulsive colour and pungence in its use, it often proves very serviceable.

Zinc pans have been much recommended for use in dairies, as the milk speedily coagulates in them, and the quantity of cream is great: but if the milk become sour while in them, the acid acts upon the zinc, and affects perhaps not poisonous compounds. Upon the whole, white porcelain vessels, kept thoroughly clean, are the best material for milk-vessels.

ZINGIBER OFFICINALE.—(Ginger), Medical Properties of. The native country of this plant seems unknown, though Goebbels asserts that it is Guiana. It is however extensively cultivated in China, Java, and the East and West Indies. From the cultivated plant alone is the ginger of commerce procured. Of this there are two varieties, the black and white; but some writers affirm that these are the produce of two distinct species, while others ascribe the difference of appearance to diversity of treatment after the rhizome is dug up. The rhizome or root-stock is perennial, but it is only that of a young plant, or the annual shoots from an old one, which are met with in commerce. When first dug up, the colour internally is red. These, when prepared, are mostly used fresh, or preserved in sugar, and constitute the sweetest known as preserved ginger. This, when sent from the West Indies, is in small round, tender pieces; when from the East, larger, flat, and stringy portions: the former is preferred.

Black ginger is stated to be the rhizome dug up,caled in hot, water, and dried in the sun. White ginger is also described as calced, and then scraped to free it from the skin, then dried, which last operation is said to be effected by artificial heat, but probably mostly by the sun. Both kinds are very liable to the attacks of an insect: to prevent these attacks the rhizomes are dried in the sun externally, and in a solution of lime, of which often adhere to the surface. To cause black ginger to resemble the white it is bleached, after its arrival in this country, in a solution of chloride of lime, or exposed to the fumes of burning sulphur. This impairs the activity of the article.
Ginger occurs in commerce in pieces termed races, of various shapes, but generally flatish, branched, lobed, or palmated, rarely more than four inches long. The unscraped has a wrinkled epidermis; the scraped is devoid of this covering. Jamaica ginger, which is most esteemed in this country, occurs in races larger, rounder, and thinner than the other kinds; externally of a yellowish white, internally of a yellower hue. The taste is agreeably aromatic and pungent, but this is lost with age, so that old pieces are worthless, as are also portions which have been digested in alcohol to form essence of ginger. Ginger when chewed excites a flow of saliva; the powder applied to the nostrils causes sneezing. The quantitative analysis of 100 parts of ginger has been given by Bechols:—

Morin's analysis yields also acetic acid, acetate of potash, and sulphur; while the ashes give numerous metallic salts and alkaline salts.

The volatile oil is of a pale yellow, lighter than water; taste at first mild, then hot. The soft resin, obtained by digesting the alcoholic extract of ginger first in water, then in alcohol, and evaporating the ethereal tincture, is not quite analogous to the principle Zingiberin, procured by Berol, and by him termed peppermint. This last is got by submitting ginger directly to the action of sulphuric acid. Berol recommends many preparations of this principle, but, except from their smaller bulk, it is difficult to perceive what advantage they possess over common ginger and its preparations. Ginger is an aromatic stimulant of considerable power. The effects are greater on organs with which it comes into direct contact than on remote ones. Thus, when chewed, it is a powerful saline, and relieves tooth-ache, rheumatism of the jaw, and also relaxed uvula. When received into the stomach, it promotes digestion in languid habits, and relieves flatulent colic. Gouty subjects are much benefited by it, and for such persons no form is more beneficial than that of preserved ginger taken at dessert after a mixture of viands. But it has the disadvantage of impairing the flavour of the wine taken at the same time.

The action of ginger on remote organs is greatest on the mucous membranes. Hence the lungs are markedly excited in the relaxed and suffocative catarrh of old people. The mucous membranes of the urino-genital organs are also excited by it in languid habits; many females receive much advantage from the domestic preparation termed ginger-tea. Some headaches of a sympathetic kind, originating in irritation of the intestinal canal, are often relieved by it. A poultice of scraped ginger, to which warm water has been added, forms a substitute for a mustard poultice, and often relieves headache when applied to the forehead. Ginger-beer is often a grateful beverage in summer heat, but with some persons it disagrees; this is owing to the sugar, for if made without it, it agrees with such persons well. Lemon-juice, when taken with sugar, often disagrees, as for example with pancakes. The lemon-juice alone is most wholesome.

ZUMALACARREGUL. [Spears, P. C., p. 360.]
